DOUBTLESS all will agree that an occasional survey of the clinical signs and their interpretation, which form the groundwork of our professional opinions, is of service, and that even commonplace subjects, if they happen to be of practical clinical interest, are deserving of our renewed attention. I have not, I fear, much that is new to say about heart murmurs in what I may call their pseudo-form; but if an excuse is necessary for the subject of this paper it will be sufficiently supplied if I succeed in showing that we are not standing still, and that the last word has not yet been said on functional heart murmurs. It is often urged that the study of the physical characters of murmurs is unprofitable, as everyone knows the significance of a morbid sound occupying a given position in the cardiac cycle; and it is further urged that the murmur, in conveying to the mind of a practitioner the impression that the patient is suffering from mitral or aortic disease, as the case may be, conveys precisely the same information to all, and in doing so has, so to speak, served its diagnostic purpose, and there is an end of it. Obviously this view is unscientific, because narrow, and tends to shut the door against further research; indeed, it forecloses discussion, and places the seal of finality on points which are still open to opinion. That murmurs are not always evidence of valvular disease and are seldom the measure of its extent are truths that are not sufficiently borne in mind in clinical diagnosis. And beyond question our stethoscopes often tell us too much or too little—too much if they constrain us to condemn a patient who has little, if anything, wrong with him; and too little if they suggest the bare fact alone of a certain valvular defect without an inkling of the nature or extent of the damage. The question that naturally occurs to us on discovering a murmur is: What does it signify? Is it organic? There are of course murmurs that bear the undeniable stamp of organic disease, as, for example, those belonging to aortic regurgitation and mitral stenosis; but the systolic murmurs of the mitral, tricuspid, and aortic areas have all a pseudo-form which resembles their prototype at times very closely. It is the characteristics of these functional murmurs that I wish to discuss. Belonging to this group there are at least three varieties which I may categorise as follows: (*a*) the cardio-hæmic or anæmic; (*b*) the neuro-typtic[2] or cardio-muscular; and (*c*) the cardio-respiratory. With the first all are familiar, and it requires but very brief reference. The murmur is, perhaps, best marked in typical examples of chlorosis, but it is by no means confined to the anæmic, and is often present in rosy and fairly-robust people. There are few delicate women, particularly if their chest walls are thin, who are without a trace of this murmur; and it is quite common to meet it in children who are below par from any cause, especially when they are examined in the recumbent posture. The hæmic murmur is usually a soft-blowing sound, and is, of course, systolic in time. It is best heard in the second interspace close to the left side of the sternum, but is often conducted into the lower reaches of the tricuspid area and downwards and outwards to the apex. In the mitral area it seldom outruns the limits of the heart walls, and is, consequently, so far as the apex is concerned, more limited than the somewhat analogous bruit of organic mitral regurgitation. The hæmic murmur is not always soft in character; it may be exceedingly rough, and is at times scratching. The roughness is often an added quality, and may be caused by unusual cardiac excitement. Particularly is the murmur liable to be rough when in addition to anæmia there is febrile excitement, as in rheumatic illness, a fact that adds to the importance of the diagnostic question. In common with other murmurs of this (functional) group, the hæmic is much influenced by the posture of the body. It is loudest when the patient is in the horizontal position, and at a minimum when the erect posture is assumed; but in some cases the difference under these conditions of posture is not great. It matters little, as a rule, whether the decubitus is dorsal or lateral. To the statement of Handford that the murmur is absent when the patient is lying on the face I am unable to subscribe. On the contrary, in several instances I have found that the bruit was loudest when the patient was placed in the prone position. It is commonly influenced by the respiratory acts, being generally loudest at the end of expiration and commencement of inspiration, and is often inaudible when the patient holds her breath at the end of forced inspiration. The physical causes of the cardio-hæmic murmur are no doubt still in dispute, but as I do not intend at present to discuss this point I shall content myself with the remark that I believe it to be the result of vibrations generated in the conus arteriosus of the right ventricle, at least in the cases in which its maximum occupies the second and third interspaces close to the sternum on the left side.[3] The question arises: For the murmur of what organic lesions may the hæmic bruit be mistaken? To which the reply is readily forthcoming. It may be supposed to indicate roughness or thickening at the aortic orifice, or perhaps mitral or tricuspid regurgitation. But, to be practical, it is most frequently mistaken for organic aortic and mitral systolic murmurs. I have been much impressed with the frequency with which organic aortic systolic bruits begin in the third left interspace close to the sternum, where they may be clearly audible for a considerable time before they spread into the right second

[2] I have ventured to suggest this name from neuron and tupto as convenient and fairly expressive.
[3] It is only reasonable to suppose that under certain conditions mitral incompetency takes place in anæmia, when the murmur will be audible in the mitral area.

Digitized by Google

interspace, or even before they are distinct in the mid-sternal region. For example, one of the first indications of gouty heart mischief in the contracting form of kidney disease may be a rough, often scratching bruit, best heard in the interspace below the third rib, close to the sternum. This murmur is at first audible over a very limited area, though not infrequently it extends down to the interspace below (fourth). I have known this murmur precede the appearance of albumen in the urine by two months, and on several occasions it has given the clue to the diagnosis of chronic Bright's disease, a diagnosis that is still further suggested by the accompanying rapid and high tension pulse. I repeat that hæmic murmurs may be erroneously taken to indicate organic mitral regurgitation, and endocarditis and atheroma at the aortic orifice the results of rheumatic, gouty, and possibly malignant endocarditis. The diagnosis is often difficult, and in few cases can be decided upon physical signs alone, yet attention to the character and behaviour of the murmur under test of careful examination may be of signal service. The true organic mitral systolic bruit usually extends beyond the apex; the hæmic rarely does, unless the anæmia is very pronounced. The organic bruit is not much influenced by posture; the hæmic varies markedly; the organic is only slightly modified by the respiratory acts. It is usually loudest at the end of expiration, and diminishes as the expanding chest wall separates the stethoscope from the heart in deep inspirations; but in no case, as far as I am aware, does a long breath (even when held) entirely conceal an organic bruit, whereas it is quite common for hæmic murmurs to disappear under these circumstances.

The fact that the hæmic murmur may be rough in quality is not, I am inclined to think, generally known; indeed, it is so usually credited with the properties of softness, and of undergoing abatement under the stimulus of exertion, that upon these points it stands or falls. It is obvious that we must hesitate before we condemn a patient, should he be the possessor of a murmur, as the subject of organic heart mischief because of the quality of roughness, and because it does not decline on exertion, for in truth the hæmic bruit often becomes louder and harsher on exertion. This change in the character of the murmur may usually be ascribed to the supervention of the shock-bruit—the neuro-typtic murmur presently to be described—as the result of excited muscular action. In addition to a modified hæmic bruit there may then be audible a rough buzzing sound, which is best heard at the commencement of the systole, and is loudest in the third interspace. The union of these pseudo-murmurs is common, and may closely simulate organic disease. Even the act of sitting up will at times induce this combined bruit, for the heart of an anæmic patient is easily excited. It is often audible in the left interscapular region, but it generally lingers here only so long as there is excitement, and disappears as the heart returns to its normal rhythm. This alliance of murmurs may be very puzzling, and many a young heart is condemned—I had almost said "unheard"—when the disturbance is purely functional. The difficulty is particularly great when, for example, we have to do with a nervous young person whose history is not entirely free from a suspicion of rheumatism. The fact that perfect rest—say, for ten or fifteen minutes, when the heart is reduced some twenty or more beats—modifies the bruit considerably, robbing it of its roughness and leaving the apex free, is very suggestive of functional disturbance. Hearts belonging to this group (combined hæmic and neuro-typtic) as well as to the next (neuro-typtic) possess a highly nervous mechanism, and are subject to a form of palpitation or over-action of which the patient may be entirely ignorant. To this excited action the morbid sound may be ascribed. The neuro-typtic bruit is of the greatest importance and is very often responsible for grave mistakes in diagnosis. I have known the life of an able and busy surgeon embittered in the belief that he was suffering from advancing mitral disease—he heard the murmur himself with the double stethoscope, and his neighbour confirmed the diagnosis; and in another instance I was called to see a medical man who had been confined to bed for a month with a supposed attack of endocarditis.

But it is chiefly in connexion with life assurance that mistakes arise. It has frequently been my lot to encourage and reassure by a hopeful opinion nervous young men who were rejected for life assurance on the medical report upon the condition of their hearts. I need scarcely add parenthetically that in attempting to establish under these circumstances the patient's confidence in himself, I have always been careful to avoid doing so at the expense of the reputation of the medical referee by recognising the existence of the heart mischief while expressing the hope that it would prove to be functional and temporary. Other cases have come under my notice apart from the question of life assurance, and, with rare exceptions, the patients have sought advice on account of their hearts. I have said that the patient is usually ignorant of the cardiac excitement or palpitation that accompanies the functional murmur I am about to describe; but this is only partly correct, for, though unaware of the existence of chronic palpitation, he is conscious of a feeling of discomfort of which the palpitation is probably the cause. The following case is fairly typical.

CASE 1.—A man aged fifty, holding a position the duties of which were chiefly clerical, consulted me for pains &c. in the chest and legs. He was a very nervous man, and after beating about the bush for some time stated that he had been the subject of heart disease for upwards of eleven years. It was with some degree of reluctance that he allowed me to examine his chest, as he had never submitted to examination before, owing to a morbid dread of having his fears confirmed. I anticipated an easy task, fully expecting to be able to dismiss from his mind all solicitude for the future; for, as a rule, a nervous patient who diagnoses his own case has absolutely nothing the matter with his heart. I found, however, that I was mistaken; for on auscultation I discovered a loud systolic murmur audible at the apex, but loudest at the union of the fourth rib with the sternum. The pulse-rate was 100 to the minute, and the apex beat was a somewhat violent shock. It was difficult to localise, but it was not displaced. The murmur was of a buzzing or whizzing character, and was only conducted a short distance beyond the apex. It was very distinctly audible with the single stethoscope, though loudest when the double was employed. After resting on his back for upwards of twenty minutes, when the pulse-rate was reduced to 86, it was observed that the shocking action and the murmur had absolutely disappeared. They both returned, however, on allowing him to stand up and talk about his symptoms. I formed the opinion that the bruit was the result of sonorous vibrations conducted to the stethoscope on account of the peculiar ventricular shock, which produced a somewhat sibilant buzzing murmur, and that there was no mitral incompetency.

A number of cases have come under my notice which resemble the above more or less closely, but I shall only refer to a few as illustrating different phases, particularly with reference to the maximum point of the murmur.

CASE 2.—A man aged thirty-five, the subject of facial palsy, stated that his medical man had discovered his heart was "wrong" about four years previously. He was an extremely nervous man, and complained, among other symptoms, of almost constant palpitation. Under examination the heart was excited and jerky (120 in the minute), and there was an apparent increase in the area over which the impulse could be felt and seen. A well-marked systolic murmur was audible at the apex and was conducted about two inches to the left. Its maximum was just above the apex beat. The murmur was rough and was rendered less distinct by pressing the stethoscope firmly on the chest. It entirely disappeared even during excitement, when he held his breath after a deep inspiration, and when he lay on the right side; nor was it any longer audible when the heart settled down after a prolonged rest.

CASE 3.—A young man aged twenty-two was sent to me by his medical attendant for an affection of the heart. He complained of dyspepsia, shortness of breath on exertion, and a sensation amounting at times to pain in the præcordium. The heart was rapid (about 100) and the impulse was distinctly heaving. There was no displacement of the apex. A loud systolic murmur was audible along the left border of the sternum from the second to the fifth interspaces. It was rough and vibrating at its commencement, and soft and blowing towards its termination. It was loudest in the fourth interspace and was feebly audible at the apex, in which area it became less distinct on placing him on his left side, whilst as the result of rest it receded altogether from the apex and remained limited to the left border of the sternum. On the two or three occasions on which I examined this case the murmur, though reduced in intensity and extent of area over which it was audible by rest, did not quite disappear. It is only fair to say that in spite of the repose the heart remained rapid and excited; in other words, that it did not respond satisfactorily to rest.

Digitized by Google

It is common to find cases of this kind among children, but here the neuro-typtic bruit is usually associated with the true hæmic murmur—a fact that should be borne in mind when applying the repose test, for as the heart settles down the anæmic part of the bruit may become louder as the shock-produced sound diminishes. The fact, however, as I have already remarked, that the apex is left free from murmur as the result of rest is of great diagnostic value. In children it is, unfortunately, very difficult to manipulate the patient so as to abolish all agitation from the impulse, for the peculiar vibrating shock that would seem to underlie the murmur is apparently very easily aroused. I have often longed to examine the case during sleep, and I suspect some cases could only be cleared up in this way. It is also worthy of note that this murmur is not rendered more marked, but is rather lessened, by placing the patient on the left side, a manœuvre that nearly always intensifies organic bruits belonging to the mitral area. As a rule, in cases in which the neuro-typtic murmur is well marked, the morbid sound is audible whenever the patient is examined, under even slight degrees of excitement, in the erect posture, but in the following case the murmur disappeared entirely after a few weeks' rest and treatment. (Bromide of potassium and arsenic, with rest, were prescribed.)

CASE 4.—An athletic young man aged twenty complained of discomfort about his heart, with palpitation and shortness of breath on exertion. He was highly nervous. The apex beat was somewhat diffused, and was a little displaced to the left. It communicated a distinct shock to the hand, and the heart was rapid (90). A low-pitched, burring, systolic murmur was audible at the apex, but was not conducted towards the left, though it could be traced towards the right as far as the sternum in the fourth and fifth interspaces. After a few minutes' rest on the back it entirely vanished, but not until the cardiac excitement subsided. When examined a month later the murmur was no longer audible.

I pass now to a form of pseudo-murmurs that has long puzzled clinical observers. I refer to the so-called cardio-respiratory murmur. This adventitious sound is very common in nervous people during inspiration, but is frequently audible during the whole of the respiratory cycle. It is short and whiffing, and corresponds in point of time, as a rule, with the first sound. It can scarcely be said to favour any particular area of the præcordium, though it is perhaps most frequently audible in the neighbourhood of the apex, either to the right or to the left of the heart, or it may be below it, though it is often in the true mitral area itself. At times it can be heard to the left of the great vessels at the base, or, again, in the mid-sternal region between the fourth ribs, or in the aortic area, or beyond the sternum on the right side in the neighbourhood of the right nipple. These situations represent the positions in which the murmur is audible in different cases, for in the individual it seldom varies, but confines itself to a particular part of the heart area under certain circumstances. I have ventured to account for the cardio-muscular or neuro-typtic murmur by the shock or muscular vibration theory. To explain the cardio-respiratory bruit, on the other hand, it seems necessary to suppose a sudden reduction in the volume of the heart as the result of rapid ventricular contraction, the consequence of which is that the air is drawn in from the tubes, and thus the blowing or whiffing sound is produced. The following case I adduce as perhaps the most striking example of the cardio-respiratory murmur with which I have met.

CASE 5.—A man aged fifty-two was sent to me by a medical friend as a case of aortic disease. The patient stated that he had been in good health prior to an attack of pneumonia of the right lung some seven years before. This illness left him in a weak condition for a considerable period. Two years later he noticed beating in the epigastrium, and still later palpitation, with frequent intermissions. Then he became very nervous, and on one occasion he fell in the street during an attack of palpitation. After this his heart disturbance grew worse, and pains in the left side of the chest, shoulder, and down the left arm (pseudo-angina) were added to his other symptoms. At the time he came under observation the pain was a decided feature, and recurred two or three times a day, usually as the result of exertion. He was a tall, thin man, with a nervous, excitable temperament. The heart was rapid (generally about 90) and the impulse was diffused and heaving. The apex, as far as it was possible to localise it, was below the fifth rib, an inch and a half below and half an inch to inside of the left nipple. On auscultation when the patient was standing a loud systolic blowing or whiffing bruit was audible to the right of the sternum in the third, fourth, and fifth interspaces. The point of maximum intensity was in the fourth interspace, immediately below the right nipple; but the murmur was distinctly to be heard over an area which could be covered by a small hand, reaching from the right border of the sternum beyond and below the nipple. It was not audible at any other part of the heart region. It was loudest during the latter part of inspiration and grew weaker as the air left the chest, but was quite inaudible when the patient held his breath at the end of a long inspiration. The murmur at once diminished in intensity when the recumbent posture was assumed; thus, when lying on the back it was only audible towards the end of inspiration, whilst it disappeared entirely when on the right or left side. This murmur was quite distinct during the whole of the respiratory cycle when the patient was sitting, but it was noticed that after a prolonged rest in this position it became rapidly less and less distinct, until finally it vanished altogether. The brachial artery at the elbow was prominent and tortuous (atheromatous). There was marked pulsation of the abdominal aorta. To sum up the case briefly. A man over fifty was thrown out of a good situation on account of palpitation, with pain and discomfort in connexion with his heart, and on auscultation a loud systolic murmur was audible to the right of the sternum in the third, fourth, and fifth interspaces. The murmur simulated imperfectly the murmur of obstructive aortic disease. It was, however, audible outside the aortic area; it was not conducted over the manubrium sterni, and it became inaudible when the patient held his breath and when he lay on either side. It was, therefore, not an organic murmur. Its distribution, its soft, whiffing character, its crescendency during inspiration, and its total disappearance on altering the posture of the body, even under excitement, distinguished it from the murmurs to which reference has already been made.

In the following case the murmur possessed similar properties, but occupied a different position on the chest wall.

CASE 6.—A young man aged thirty consulted me for sexual and other nervous disturbances. There was a sharp, somewhat violent heart impulse (apex), which seemed a little below and to the left of the normal situation. A loud, soft, systolic murmur was audible in the sixth interspace below the extreme apex beat. It was loudest towards the end of inspiration and faint during expiration, whilst it disappeared when the patient held his breath at the end of a forced inspiration and when he lay down.

In another case, one of old-standing organic heart disease, in which pronounced double aortic and systolic mitral bruits were audible, and the heart was markedly hypertrophied, a similar soft, whiffing, systolic murmur could be heard quite independent of the organic murmurs, in the seventh interspace below and to the outside of the apex line. This murmur was only present when the patient lay on his left side at a certain very constant angle. On failing to attain this point, or on over-reaching it a little, the murmur could not be heard.

I now come to an interesting case, which I must describe rather more at length, as it possesses considerable interest from a life assurance point of view.

CASE 7.—A man aged thirty-two, following a sedentary occupation, came to me about his heart because he had been rejected on two medical examinations for life assurance. He had always been nervous, and of late his nervous symptoms had increased. For two and a half years he suffered occasionally from palpitation and violent action of the heart, but he had never known what it was to be breathless on exertion. He was able to take long walks and climb hills, and he frequently rode a bicycle. His father died suddenly some six years previously from thoracic aneurysm, and to the shock received at the time he ascribed a good deal of his nervousness, and especially his heart symptoms. He was examined in 1886 for life assurance (two years before his father's death), when his proposal was accepted. In January, 1893, he desired to add to the policy, but was rejected on account of his heart. In March, 1894, he made a further application, when another (independent) adverse report was made. He was a tall, thin, fair man, highly intelligent, but very nervous. He never suffered from rheumatism. The heart was rapid (110) and jerky in action. The apex beat was beneath the fifth rib, about half an inch to the inner side of the nipple line. Examined standing, a loud murmur was audible at and a little to the left of the apex. It was systoli

Digitized by Google

in time and seemed to be formed of two bruits combined. It commenced as a rough buzzing sound and terminated in a soft whiff or blow, and could be traced up to the fourth rib beside the sternum, where, however, it became very feeble. There was also a loud blowing systolic murmur in the second interspace to the left of the sternum. During a slowly drawn, exaggerated inspiration the buzzing portion of the apical murmur became feebler, whilst the whiffing or terminal part grew louder. On the other hand, towards the end of expiration the rough part of the murmur increased in intensity, whilst the soft blowing part was reduced to a minimum. After half an hour's rest, when the heart was reduced to 85, the murmur vanished altogether from the neighbourhood of the apex except towards the end of a long inspiration, when a short systolic whiff could alone be detected. The murmur in the pulmonary area continued after all cardiac excitement had abated, and was obviously hæmic.

In this case the three functional murmurs united to produce stethoscopic signs that could with difficulty be distinguished from organic heart disease. The hæmic was represented by the bruit in the left second interspace, the neuro-typtic by the rough buzzing sound in the apical region, and the cardio-respiratory by the soft whiff which brought the systolic murmur to a termination. But the application of what I may call the rest, the positional, and the respiratory tests justified the diagnosis of functional disturbance. Not infrequently the murmur is at a maximum when the breath is held at the end of a deep inspiration, and this should be borne in mind.

CASE 8.—A woman aged twenty-seven, stout and full-blooded, consulted me for headaches and pain in the chest and left side. In searching for a cause of the latter pain I came upon a loud systolic murmur about an inch to the left of the heart apex, which was in its normal position. The murmur was short and blowing; it was best heard in the ninth and tenth interspaces in the posterior axillary line, and was loudest during inspiration and at a minimum at the end of expiration. On directing her to draw a long breath and hold it the murmur became markedly intensified. There was no hæmic bruit. The cardio-respiratory bruit is not always systolic in time, but may follow the first sound like an echo.

CASE 9.—A man aged sixty-nine, highly nervous but well-preserved, complained of palpitation, some pain in the left side, and increased frequency of micturition. He was nervous about himself, and suspected diabetes. He informed me that for thirty years he had been suffering from what medical men called mitral disease, but he had become used to the idea, and was not disposed to take a serious view of his heart condition. The heart was rapid (115 in the minute), with a jerking action. The apex was a little below and to the left of the normal position. Examined standing, a loud murmur was audible at the apex and to the right and left of this point; it was short and whiffing, and synchronous with the first sound, and was loudest during inspiration, but became much less distinct when the breath was held. When he lay down the bruit to the right of the apex in the fifth interspace was no longer synchronous with the first sound, but followed it, just coming in before the second sound, which was normal. At the apex and to the left this separation from the first sound was not recognised. After resting on the back for a while the heart came down to 84, and the murmur disappeared.

In some of the cases I have related there was more than a suspicion of cardiac hypertrophy, as evidenced by displaced apex beat. Indeed, it might almost be said to be the rule to meet with the impulse slightly lower and further out than the normal situation in cases in which the neuro-typtic murmur is well marked. In other words, it is not uncommon to meet with hypertrophy, real or apparent. Whilst admitting the possibility of some slight degree of hypertrophy, arising out of chronic palpitation or over-action, I am decidedly of the opinion that the increased area of impulse in these cases cannot be regarded as a sufficient indication of hypertrophy or dilatation; for even in the case of habitually quiet, normal hearts, a little excitement or exertion will at once cause an apparent outward displacement of the apex beat, which in some instances will continue in the new position for a while after the pulse has fallen to its normal rate. This point requires further investigation, for it is obviously of importance to determine the size of the heart, a task of considerable difficulty in cases of nervous palpitation. In very few instances was I able to satisfy myself that the area of percussion dulness was at all increased, and in none did I meet with increase in the area of deep dulness. It will possibly be thought that the explanation given above of the so-called shock and cardio-respiratory murmurs are inadequate, and so they may be; but I am not so much concerned just now with the theory of their production as I am to bring under the notice of the profession the fact that functional heart murmurs very often simulate organic disease. The accompanying table shows the chief clinical features of the various murmurs:—

Table showing the Characteristics of Different Murmurs.

—	Organic mitral.	Hæmic.	Neuro-typtic.	Cardio-respiratory.
Physical character.	Varied, soft, or rough.	Usually soft; may be rough.	Rough, scratching, whizzing.	Soft, whiffing.
Position of maximum.	Apex and conducted towards left.	Pulmonary area rarely beyond apex.	Little above and to right of apex. Loudest in fourth interspace close to sternum.	Varied in position; often not referable to any particular area.
Posture test.	But slightly influenced by change of position. Loudest when lying on left side.	Loudest when lying on the back. Faintest when standing.	Loudest when standing; often disappears when lying on either side.	Do. Do.
Respiratory test.	Loudest at end of expiration, but not much influenced by respiration.	Loudest at end of expiration, often inaudible at end of deep inspiration.	Do. do.	Loudest towards end of inspiration, faintest at end of expiration. On holding a long breath will often disappear, but may be intensified.
Rest test.	Not much affected by exertion. Well-marked after prolonged rest.	Loudest after rest.	Loudest after exertion or any excitement. Inaudible after prolonged rest.	Loudest during excitement, may be inaudible after rest.

Saville-place, Newcastle-on-Tyne.

ON THE

PRESENCE OF TYPHOID BACILLI IN THE URINE OF PATIENTS SUFFERING FROM TYPHOID FEVER.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY;
AND
SURGEON-MAJOR D. SEMPLE M.D.U. IRELL.,
ASSISTANT PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

THE fact that typhoid bacilli are to be found in the urine of patients suffering from typhoid fever is not a new fact. It is, however, a very important fact, and for these reasons. First, if it is true that the typhoid bacilli are present in the urine of patients suffering from typhoid fever, and if, as we shall see, typhoid bacilli are generally absent from the fæces, it will be evident that it is the urine, and not the fæces, of patients suffering from typhoid fever which is responsible for the spread of typhoid infection. Secondly, if typhoid bacilli are constantly present in the urine of typhoid patients, it may be possible to diagnose the presence or absence of typhoid fever by undertaking a bacteriological examination of the urine. Thirdly, if it is true that typhoid bacilli are constantly present in the urine in cases of typhoid fever while they are generally absent from the fæces, it will be evident that the conception of typhoid fever upon which the ordinary clinician proceeds is an entirely erroneous one. It will be convenient to proceed immediately with the discussion of this question. The theory of typhoid fever, which is currently held, and currently acted upon, is the theory that typhoid

Digitized by Google

fever is an "intoxication process," much in the same way as cholera is an "intoxication process." In other words, it is assumed that the typhoid bacillus vegetates in the intestine, that it effects a lodgment in the intestinal walls, and that the poisons which are elaborated by the bacilli are absorbed into the system from the intestine. The systemic disturbance which characterises typhoid fever is attributed to this absorption. This theory of typhoid fever is brought into harmony with notorious bacteriological facts by the assumption that there is a certain leakage of typhoid bacilli from the intestine into the system. This leakage theory is supposed to dispose of the fact that typhoid bacilli are invariably found in the spleen and mesenteric glands of patients suffering from typhoid fever. Now, this "intoxication" theory of typhoid fever was originally based upon the fact that a bacillus which is morphologically indistinguishable from the typhoid bacillus is found in large quantities in the stools in every case of typhoid fever. Subsequent investigations, however, showed that this bacillus which predominates in the intestinal floor in cases of typhoid fever can be distinguished from the true typhoid fever bacillus by a series of chemical differences. The bacillus which is found in such large quantities in the stools of patients suffering from typhoid fever is therefore not the true typhoid fever bacillus. It is the bacillus which is known by the name of "bacillus coli communis." Recent research has, therefore, been directed to the question as to whether, in addition to the bacillus coli communis, the true typhoid fever bacillus is not also to be found in the stools of patients suffering from typhoid fever. The following are the results of Wathelet's careful examination of this question. The true typhoid fever bacillus was detected in the stools of only four of the twelve cases of typhoid fever which were studied by this observer. In the case of these four patients the typhoid fever bacillus was detected only four times in a total of twenty-four examinations; and even on these four occasions the true typhoid fever bacillus was outnumbered by the bacillus coli communis in the proportion of about three to one. In the case of the other eight cases of typhoid fever the bacillus appeared to be absent from the stools throughout the whole course of the disease. Wathelet has further shown that if the bacillus typhosus and the bacillus coli communis are implanted into one and the same tube of nutrient broth, the bacillus coli communis will outgrow and kill off the typhoid fever bacillus even when at the outset an enormous numerical preponderance is given to the typhoid bacillus over the bacillus coli communis. Again, Wathelet has shown that whereas the bacillus coli communis will flourish in a nutrient medium containing the toxines elaborated by the typhoid fever bacillus, the typhoid fever bacillus will not grow in a nutrient medium containing the toxines elaborated by the bacillus coli communis. If this holds true in every case—and it has seemed to hold true in the few test-experiments we have performed—we are evidently in a position to infer on *a priori* grounds that typhoid fever bacilli will be absent from the intestine whenever, as in the case of typhoid fever, we have to deal with a multiplication of the bacillus coli communis in the intestine. Both *a priori* reasons and actual observations, therefore, point to the absence of typhoid fever bacilli from the intestinal tract, and therefore the symptoms of typhoid fever cannot be interpreted as a result of the absorption of typhoid toxines from the intestine. We are therefore compelled to seek for a new theory of typhoid fever, and if typhoid fever is not the result of an intestinal intoxication process, we must evidently seek to explain it as a result of a blood infection. This is, if we understand it aright, the theory of typhoid fever which has recently been put forward by Sanarelli under the auspices of Metschnikoff. We have to see whether typhoid fever can be explained upon the basis of this theory. And evidently the first thing to be explained in the case of typhoid fever is the turgidity of the spleen and the presence of typhoid bacilli in the splenic tissue. Now, this turgidity of the spleen and this presence of micro-organisms in the splenic tissue is an invariable accompaniment of every septicæmic process. We find it in the case of such blood infections as anthrax in cattle and spirillum fever and malaria in man. And we have the explanation of this phenomenon in the experiments of Werigo, which show that the introduction of any foreign particulate matter into the blood invariably results in a deposition of that particulate matter in the spleen (and other internal organs), and in an aggregation of polynuclear white blood-corpuscles round the foreign particulate matter, and, finally, in a process of phagocytosis. Everybody who has a rabbit, and a little carmine, or any bacterial culture at his disposal can readily verify these facts for himself. The enlarged spleen and the presence of bacteria there are thus quite in harmony with the theory of a blood infection in typhoid fever. The fact that the white blood-corpuscles are diminished[1] in the circulating blood in typhoid fever is also in harmony with this explanation. We have further in connexion with typhoid fever to account for the eruption of pink spots on the skin. These were inexplicable on the intoxication theory of typhoid fever. They are, however, of the easiest explanation if we make the assumption that typhoid fever is characterised by a blood infection, for here, as in other cases, we may instance the skin eruption in the case of human glanders, the spots evidently correspond to lodgments of the bacteria in the capillaries of the skin. This interpretation of the skin eruption in typhoid fever has been borne out in the case of typhoid fever, just as it has in the case of glanders, by the fact that the specific bacteria have been cultivated from the spots. We have been able to confirm this observation in one of the cases of typhoid fever reported below.

The intestinal symptoms of typhoid fever are of somewhat uncertain explanation. Possibly they are to be explained, as Sanarelli explains them, as a specific effect of the typhoid fever toxine on the adenoid tissue of the intestine, and of the subsequent invasion of that tissue by the bacillus coli communis. We have, however, not been able to verify Sanarelli's observation that the injection of typhoid fever toxine will produce a swelling of the Peyer's patches in the guinea-pig. On the other hand, the inflammation of the Peyer's patches might evidently be due to a lodgment of typhoid bacilli in the adenoid tissue comparable to that which occurs in the capillaries of the skin. We thus see that the theory of a blood infection will account for the intestinal phenomena just as well as the theory which locates the source of the disease in the intestine. The occasional presence of typhoid fever bacilli in the intestine is easily accounted for by assuming that a certain number of the typhoid fever bacilli escape through the intestinal wall into the intestinal contents. The relapses which occur in typhoid fever may be compared with the relapses which occur in spirillum fever, which is a typically septicæmic process. In both cases the cause of the relapses would be some incompleteness in the original phagocytic reaction. Such incomplete phagocytosis would be followed up by a cultivation of the typhoid fever bacilli in the spleen, and ultimately by a dissemination of these bacteria through the body by means of the blood current. This would be evidenced by a fresh outcrop of spots upon the skin.

In addition to the points which have just been touched upon, we may refer to two others, which, though they have been comparatively neglected, throw an important light upon the pathological processes which are associated with typhoid fever. The phenomena in point are the presence of so-called "miliary lymphomata" in the kidney and the presence of the typhoid bacilli in the urine. We have had no recent opportunity of studying the miliary lymphomata which are described as occurring in typhoid fever, but they are probably quite comparable to the miliary lymphomata which are described as occurring in the spleen in cases of spirillum fever, and to the miliary lymphomata which are produced by the injection of fairly resistant bacteria, such as tubercle bacteria, into the blood. Such lymphomata correspond to aggregations of white blood corpuscles around bacteria which have lodged in the capillaries. They are a repetition in small of the aggregations of phagocytic white blood corpuscles which are seen on a far larger scale in the spleen. Lastly, with regard to the presence of typhoid fever bacilli in the urine. Even if typhoid bacilli were found in the urine only in occasional cases their presence there would be a strong argument in favour of the theory of a blood-infection and against the intestinal intoxication theory. But the argument in favour of the septicæmic theory of typhoid fever becomes irresistible if it

[1] It may be pointed out incidentally here that the paucity of white blood-corpuscles in the blood probably stands in some connexion with the fact that epistaxis is of frequent occurrence in typhoid fever. This epistaxis—if we may judge from a great many observations which one of us has made of the condition of blood-coagulability—is almost certainly an indication of a diminished blood-coagulability such as can be obtained by the injection of particulate matter into the blood. In an experiment made by one of us, the coagulation time of a dog's blood in the standard capillary tube was reduced from three minutes to fifteen minutes by an intra-vascular injection of carmine particles.

Digitized by Google

can be shown that the typhoid fever bacilli are almost always found in the urine in cases of typhoid fever. With a view to ascertaining this point we have examined the urine in the the following typical cases of typhoid fever.

CASE 1.—A man aged thirty-five had a very severe attack of typhoid fever with a relapse, which was accompanied by a typical rash. A specimen of urine was taken on the seventh day of the relapse while the temperature was at its highest, reaching 103·6° F. The patient made a good and steady recovery. The disease was contracted at the Cape, and the primary attack lasted quite five weeks.

Bacteriological examination.—The urine was passed directly into a sterilised bottle. Plate cultivations were made from it a few hours afterwards and a considerable number of typical colonies appeared on the plates. These were planted out into gelatine, and typical stab-cultures were obtained. Tubes of milk, ordinary broth, and 2 per cent. cane sugar and chalk broth, were also inoculated. There was no curdling, indol production, or gas evolution.

CASE 2.—A girl (aged fifteen) had a mild attack of typhoid fever. The specimen of urine was taken on the fourth day after admission to the Royal South Hants Infirmary during the supposed third week of the disease. No rash was seen whilst she was in the hospital, and the temperature had been falling since admission. She made a speedy recovery.

Bacteriological examination.—The urine was drawn off by an aseptic catheter into a sterilised bottle. Plate cultivations were made a few hours afterwards, but no typical colonies could be detected on the gelatine plates.

CASE 3.—A boy aged fifteen had a severe attack of typhoid fever, and was admitted to hospital on the eighth day. On admission he was deaf and drowsy. The stools were typical; there was a trace of albumen in the urine and there were a few doubtful spots. There was considerable bronchitis. The temperature ranged between 102 4° and 104 8° F. from the eighth to the eleventh day, beginning to decline on the twelfth day. There was an eruption of typical spots on the tenth day, and on this day a specimen of urine was taken. The patient steadily improved on the decline of the temperature, and another specimen of urine was taken on the fifteenth day. The temperature had been 99·4° that morning and 102 8° the previous evening. He is now almost convalescent.

Bacteriological examination.—First sample of urine: Plate cultivations were made, as in the last two cases, within a few hours after the urine had been drawn off by aseptic catheter. Plates inoculated with one loopful of urine remained sterile. The remainder of the urine was incubated for forty-eight hours at 37° C., and plate cultivations were then made with 0·25 c.c. A considerable number of typical colonies developed upon the plates. These were further tested as to their chemical properties as in Case 1, and reacted in every respect as typhoid. No typhoid colonies were recognised on the plates which were made from the second sample of urine after it had been incubated for forty-eight hours.

CASE 4.—This was a boy aged nine, brother of the last patient. The attack was one of medium severity. He was admitted on the tenth day of the disease. He was deaf and drowsy. He had a profuse rash and some bronchitis. His spleen could be felt. There was no albumen in the urine, and he was constipated. The first specimen of urine was taken on the twelfth day, when the temperature had commenced to decline, but ranged from 102° to 103 6° F. On the seventeenth day a second specimen was taken. The temperature then ranged from 98·4° to 99·8°. On the eighteenth day there were still a few spots to be seen. Cultivations were made from three of these. The temperature had not exceeded 99° for five days, when on the twenty-fourth day it rose to 100 2° at 8 P.M., and a relapse began. This relapse was of a mild type constitutionally, but the temperature reached 104 8° on the third day (twenty-sixth day of the disease), and there were a few spots. On the twenty-seventh day there was a profuse crop. On the twenty-eighth day (fifth day of the relapse) a few spots were still to be seen. Cultivations were made from two of these, and a third specimen of urine was taken. The temperature on this day ranged from 99·6° to 103·2°.

Bacteriological examination.—The first sample of urine was passed into a non-sterilised chamber-pot. No colonies which resembled typhoid were detected on plate cultivations made a few hours after the urine had been passed. Numerous typical colonies made their appearance on plates made with urine which had been incubated for forty-eight hours. The bacteria which were planted out from three of these colonies curdled milk, and gave the indol reaction with ordinary broth and the bubbling reaction with 2 per cent. cane sugar and chalk broth. The bacteria which were planted out from nine other colonies corresponded in all respects to true typhoid bacteria. Plates were made from the second and third samples of urine after they had been incubated in each case for forty-eight hours. The results in the second sample were negative. Typical typhoid bacilli were cultivated from the third sample of urine.

Typhoid spots.—On the eighteenth day after sterilisation of the skin three typhoid spots were punctured with a sterile hypodermic needle mounted in a piece of sterile glass tube, and plate cultivations were made. A typical colony made its appearance on one of the plates. The bacteria corresponded in all their chemical and morphological characters to true typhoid bacilli. On the twenty-eighth day cultivations were made by the same method. Several typical colonies developed on one of the plates, and cultures made from these conformed in all respects to true typhoid.

CASE 5.—This was a girl aged fourteen, sister of the last two. It was a very mild case. She was admitted to hospital on what was probably about the ninth day, with constipation and a few typical spots. Her temperature was 103° F. that evening, but fell steadily. The first specimen of urine was taken by catheter two days after admission, when the temperature varied between 98·8° and 100·6°. The temperature remained below 98·4° during the whole twenty-four hours on the thirteenth day, and has continued so since. A second specimen of urine was taken on the sixteenth day, when there had been three clear days of apyrexia. She is now convalescent.

Bacteriological examination.—A single typical colony made its appearance on plates made from the first sample of urine a few hours after it was passed. The bacteria from this colony corresponded in all their chemical and morphological characters with true typhoid fever bacilli. No typhoid fever colonies appeared on the plates made from the urine after it had been incubated for forty-eight hours. This urine had turned alkaline. A second sample of urine gave negative results.

CASE 6.—This was a girl aged nine years, a lodger in the same house as the last three cases. She had a very severe attack, and was a delicate-looking child. She was admitted on about the same date of the disease as the last case. On admission she had a temperature of 103·2° F., and rapidly became unconscious and passed her evacuations into the bed. She had a rash and a great deal of bronchitis. For a week her temperature ranged between 103° and 104·8°, and for another week between 101° and 104°, and then began definitely to decline. The first specimen of urine was taken on the second day after her admission, and the second on the seventh day after admission—i.e., on the eleventh (?) and sixteenth (?) days respectively. About the twenty-fifth day a suspicious-looking gangrenous patch appeared inside the left cheek, which spread, and was scraped out on the twenty-seventh day under chloroform, and freely rubbed with a strong solution of chloride of zinc. It now appears to be doing well. On the twenty-eighth day a purulent discharge began from the left ear, which continues. At the present time the child is distinctly better and is quite conscious. Her temperature fell to 98 8°, and only rose to 101·4° on the twenty-eighth day.

Bacteriological examination.—First sample of urine: No typhoid fever colonies made their appearance on the plate made a few hours after the urine was passed; numerous typical colonies appeared on plates made after the urine had incubated forty-eight hours. Bacteria from these colonies corresponded in all respects to true typhoid fever bacteria. Second sample of urine: Numerous typical colonies made their appearance on plates made after the urine had been incubated for forty-eight hours. Bacteria from these colonies were true typhoid bacteria.

CASE 7.—This case was under the care of Mr. Chance, to whom we are indebted for the notes, of which the following is an abstract. The patient was a woman aged eighteen, who began to feel ill a few days before leaving New York on June 13th, 1895. From the 16th to the 19th, when she landed at Southampton, her temperature varied from 103° to 105° F. After this the temperature fell somewhat for a while, but made great daily excursions. There was a fair amount of diarrhœa, a well-marked rash, and unconsciousness with delirium. The urine was taken on the eleventh day, when the temperature varied from 103 4° to 99 2° F. Death occurred without any return of consciousness on the thirteenth day.

Bacteriological examination.—Very numerous typical

Digitized by Google

colonies appeared on plates made after the urine had been incubated for forty-eight hours. Bacteria from these colonies correspond in all respects to true typhoid fever bacteria.

We thus see that in six out of seven cases examined the typhoid fever bacilli were easily detected in the urine. In view of this fact it seems to us that the bacteriological examination of the urine ought not to be neglected in any doubtful case in which typhoid fever is suspected. It is hardly necessary to do more than merely advert to the hygienic aspect of the matter. It was only a natural outcome of the intestinal intoxication theory of typhoid fever that the greatest precaution should have been enjoined with regard to the stools of the patient suffering from typhoid fever, while the disinfection of his urine was neglected. If, however, the recent observations on the almost constant absence of typhoid fever bacilli from the stools are to be trusted, the disinfection of the fæces will have to rank not as an article of faith, but as a mere "counsel of perfection." On the other hand, the most careful attention will have to be given to the disinfection of the urine. In some cases the urine even before incubation is absolutely turbid with typhoid bacilli. In conclusion, it is our pleasant task to thank Dr. W. P. Purvis, of the Southampton Infirmary, for the notes of the clinical cases which he has furnished and for much useful assistance in the conduct of the bacteriological examinations.

Netley, Southampton.

NOTES ON THE PLAGUE IN CHINA.

BY JAMES A. LOWSON, M.B., C.M.EDIN.

So far I have met with only five cases of plague in Hong-Kong, of which four were imported from Canton. The remaining patient must have contracted the disease in Hong-Kong, but the manner of infection has not been traced. At Macao the fatal cases have for some time averaged ten daily, but according to information just received (June 12th) there are now only three or four deaths daily. Canton city was absolutely free from the disease when I was there a week ago, but the surrounding villages are suffering severely. Hoihow is likewise practically free, only one or two straggling cases being known. The news from Swatow is also favourable, my medical correspondent reporting only from three to five cases per week, but intelligence of another outbreak not far from Swatow has just arrived. This is only to be expected. Plague travels very slowly, and we may anticipate that it will pursue an erratic course through many Chinese villages for the next few years. In the villages no methods of checking its advance are ever thought of, and consequently a sort of quarantine or prevention of immigration may have to be kept up perhaps for years unless wiser counsels prevail. Amoy is declared free from plague. Immigration from Macao, Hoihow, and Swatow is still prohibited—a somewhat unnecessary precaution, especially with respect to the two last-named places.

I have been able to carry on some experimental researches in conjunction with the colonial veterinary surgeon. Pigs are but slightly susceptible to the disease. Observations made in six cases show that their temperature is not raised by feeding them on plague-infected spleens. Inoculation in the flank is followed by a rise in temperature of from 2° to 4° F. in about twenty-four hours, the site of inoculation becoming œdematous. On careful bacteriological examination of the serum from the œdematous tissue no plague bacilli were found either by the microscope or by cultivation. In our experiments on cattle two animals have been inoculated about six times each, and they show the same symptoms as [redacted] pigs. The rise of temperature, however, is somewhat greater; 100° to 101° is the normal, and a temperature of 106° is frequent. They do not lose their appetites at all. An œdematous swelling appears round the place of inoculation; but, just as with the pigs, no bacilli are found in it. The inoculations were made from the bubo direct, from culture, and from rabbits which had previously been inoculated with the disease. I only want a few cases to try now in the hope of producing immunity in the cattle, but to all appearance I shall not be able to get them here. Yessin says that in Yunnan he has proved the presence of the same bacillus in cattle plague and that it is most deadly. I think he must mean the rinderpest, which is so common in Yunnan.

Hong-Kong, June 12th.

A CASE OF BELLADONNA POISONING.

BY S. R. SCHOFIELD, M.R.C.S. ENG., L.R.C.P. LOND.,
AND
C. S. PANTIN, M.B., B.S. LOND.

THE patient, a boy aged six, was brought to the Victoria Hospital for Children, Chelsea, at 1.15 P.M. on Aug. 2nd, 1894. At noon the boy had left his home, and at 1.10 P.M. he had been brought back by some children, who said that he had fallen on his head. The boy was found to be delirious and very restless. The movements were jerky and unexpected. He would sit up successfully for some time and then overbalance backwards or forwards. He could stand and walk a little, but in a very incoördinate manner. The pupils were equal and dilated; they did not react to light. The skin was dry and apparently itching, for he constantly scratched himself. He resented being interfered with and did not recognise his mother. No external injuries could be found. The history of a fall was discredited and belladonna poisoning suspected. The boy was admitted to the hospital under the care of Dr. W. Wallis Ord. From the stomach fragments of about half a dozen belladonna berries were removed, together with numerous seeds. No food was found in the stomach. Despite the struggles of the patient the washing out was continued until water returned without any seeds. For the next few hours he lay quietly in bed, apparently exhausted, but at 5 P.M. he sat up and swallowed some peptone with difficulty. He refused water. In the evening he became very restless and several times nearly fell out of his cot. He stared about him with eyes apparently focussed for distant objects, for he did not notice people who were close in front of him. The pupils remained dilated. On careful watching [redacted] was evident that in his delirium he was going through [redacted] events of the morning. After looking suspiciously round in all directions he would stretch out his hand to the screen at the head of the bed and appear to be plucking something; he would examine the supposed contents of his hand and then put it to his mouth and go through the acts of mastication and deglutition. Occasionally he put his hand to his nose, as if smelling, and once he seemed to be spitting something out of his mouth. Again he would seem to be picking up something, which he would throw into the air and catch or throw away to a distance. He called his late companions by name and made remarks bearing on the subject of the berries, such as "Have you got it?" "You said they were not cherries"; "Are there any stones in them?" "Give me one to taste"; "Eat that and I'll tell your mother." He gave the impression of being quite happy. The skin was dry, and his speech suggested dryness of the mouth. He frequently rolled his tongue about. The face was flushed, but there was no rash. The pulse was 120, regular, and of low tension. He passed urine unconsciously several times, but the [redacted] der remained distended until relieved after a fomentation. [redacted] morphia injection of one-tenth of a grain sent him to sleep for several hours. Next morning consciousness began to return. He could answer questions in a muddled way. The pupils remained large, but reacted slightly to light. The motions contained a few seeds, but no berries. The following day the boy was quite well. The berries and seeds were those of atropa belladonna (deadly nightshade). The patient led the way to the spot where he had picked and eaten them.

The case seems worthy of record, firstly, on account of the difficulty of diagnosis in the face of a misleading history, and, secondly, on account of the more than usually realistic manner in which the taking of the poison was rehearsed in the resulting delirium.

AN UNPUBLISHED PHYSICAL SIGN.

BY WALTER BROADBENT, M.B. CANTAB.,
HOUSE PHYSICIAN AT THE BROMPTON HOSPITAL FOR CONSUMPTION.

BY the kind permission of the physicians at the Brompton Hospital I am permitted to publish the notes of four cases now under their care in the wards, in each of which there is visible retraction, synchronous with the cardiac systole, of the left back in the region of the eleventh and twelfth ribs, and in three of which there is also systolic retraction of less degree in the same region of the right back. In all the cases there is a definite history of pericarditis, and in three of them there are other conditions strongly suggesting an adherent pericardium. The only means of causing this retraction on both sides seems to be the diaphragm, which, if pulled upon, would have more effect on the floating eleventh and twelfth ribs than on the other more fixed ones. In cases of large heart with adherent pericardium there is a considerable area of the ventricles closely adherent to the central tendon of the diaphragm, and the powerful contraction of the hypertrophied heart must give a decided tug to this structure. That it should affect the ribs more often on the left side would be expected from the adhesion being mainly to the left of the middle line; the liver also, which is often large in these cases, may restrain the movement on the right.

CASE 1.—A youth aged eighteen years had rheumatic fever in 1890 and pericarditis in 1893. He is pale and thin, with carotid pulsation very marked in the neck. He also shows capillary pulsation. His pulse (80) is regular in force and frequency. The artery is large, and visible for two inches up the arm. The wave is sudden, large, bisferiens, and almost completely collapsing. The chest bulges on the left side from the second rib downwards. The apex beat is a very powerful thrust in the sixth space four inches and a half below and one inch and a half outside the nipple. There is systolic retraction of the third and fourth left spaces, and also of the epigastric region, and pulsation in the fifth and sixth left spaces. The apex beat does not change its position on his taking a deep breath, and moves barely half an inch when he lies on one side or the other. In the left back, between the posterior axillary and scapula angle lines, retraction, synchronous with the cardiac systole, is seen and felt in the tenth and eleventh spaces, and over the twelfth rib and just below it. In the right back systolic retraction of almost equal intensity is present over precisely the same area. The cardiac dulness is bounded above by a line from the mid-sternum opposite the fourth cartilage to the nipple; and in the sixth space extends from the right of the sternum to two inches outside the vertical nipple line. Deep inspiration only slightly decreases this area. The heart sounds are as follows: at the apex there is a blowing systolic murmur almost entirely replacing the first sound, and a long low murmur filling the diastole. Both murmurs are heard round to the back. In the tricuspid area there are a good first sound, a blowing systolic murmur, a second sound, and a blowing disastolic murmur. At the pulmonary cartilage a rough systolic murmur, slightly accentuated second sound, and a blowing diastolic murmur are audible. At the aortic cartilage there are a rough vibratory systolic murmur, a second sound, and a loud blowing diastolic murmur. In the neck there is heard a very loud vibratory systolic murmur, but no second sound. The liver is only just felt below the margin of the ribs. Respiration is almost entirely costal, and the epigastric region recedes on inspiration. There is slight dulness at the left base, and some rhonchi and crepitations are heard over the lower part of both lungs, especially the left.

CASE 2.—A girl aged eighteen years had pericarditis with rheumatic fever in 1893. She is a thin, anæmic girl with slightly flushed cheeks. Her pulse (116) is regular in force and frequency. The artery is of fair size, just felt between the beats; the wave is large and short, and very easily compressible. There is very little præcordial bulging. The apex beat is in the fifth space, an inch and a half below and half an inch external to the nipple; the sixth rib is also lifted. A presystolic thrill is felt, followed by a short powerful impulse. Slight pulsation is also visible in the second, third, and fourth spaces on the left side, and to the right of the sternum in the fourth and fifth spaces. In the epigastrium there is very slight systolic retraction. The apex beat does not alter its position on her taking a deep breath, and only moves very slightly on her turning on to either side. In the left back there is seen retraction, during the cardiac systole, of the tenth space and eleventh and twelfth ribs, with the region just below. In the right back there is a similar retraction of the twelfth rib with the space above and below. Cardiac dulness begins in the third space from the mid-sternum to the left vertical nipple line, and in the fourth space extends from half an inch to the right of the sternum to half an inch outside the left nipple line; in the fifth space it extends from three-quarters of an inch to the right of the sternum to one inch outside the nipple line. Deep inspiration does not decrease the cardiac dulness. The sounds heard are at the the apex, a short soft rumbling presystolic murmur leading up to a very loud banging first sound, and a whistling systolic murmur; no second sound is audible. The first sound and the systolic murmur are conducted round to the back. In the tricuspid area there are heard a first sound, a blowing and slightly whistling systolic murmur, and a second sound. At the pulmonary cartilage there are a first sound, a soft systolic murmur, and an accentuated and reduplicated second sound. At the aortic cartilage a loud first sound and a second sound are audible. The liver is felt two fingers breadth below the costal margin. The abdomen moves very poorly in respiration, even for a girl, and the epigastrium sinks in on inspiration. In the lungs there is tuberculous infiltration of the right upper lobe, and of the apex of the lower lobe, with some excavation. There is also slight want of resonance at the left base, with diminished breath sounds.

CASE 3.—This was a young man aged twenty-one years. In 1888 and 1890 he had rheumatic fever, and in 1892 pericarditis and left-sided pleurisy. He is fairly healthy-looking, being only short of breath on exertion. His pulse (108) is regular in force and frequency. The artery is rather large and just visible at the wrist, being nearly empty between the beats; the wave is short and large and is easily compressible. There is some præcordial prominence below the third rib on the left side. The apex beat is in the sixth space, four inches below and half an inch external to the nipple. There is a powerful thrust in the fifth and sixth spaces, with a shock at the end of systole; pulsation is also seen in the third and fourth spaces. There is slight systolic retraction of the epigastric region, but pulsation is felt on deep palpation. The apex beat appears in the seventh space when he takes a deep breath, and moves half an inch internally on his lying on the right side, and one inch and a half externally on lying on the left side. In the left back systolic retraction is seen from the tenth space to just below the twelfth rib, between the posterior axillary and scapula angle lines. On the right side the tip of the twelfth rib is seen to be drawn in during the cardiac systole. The cardiac dulness is in the third space two inches to the left of the sternum, in the fourth space from the mid-sternum to the left nipple, and in the fifth and sixth spaces from the right margin of the sternum to one inch and a half outside the vertical nipple line. This area is considerably decreased on deep inspiration. At the apex there are heard a short, loud, banging first sound and a harsh, systolic murmur, but no second sound. The first sound and murmur are conducted through the axilla to the back. Over the tricuspid area a loud first sound, a blowing systolic murmur, and a sharp second sound are audible. At the pulmonary cartilage there are heard a first sound, a systolic murmur, and slightly accentuated and reduplicated second sound. At the aortic cartilage a short first sound, a soft systolic murmur, and a fair second sound are audible. The liver is not enlarged. Respiratory movement is absent in the epigastric region and very poor in the lower abdomen. In the lungs there is diminished resonance at both bases, and the breath sounds are weak at the right base, but good at the left base.

CASE 4.—A girl aged seventeen years had rheumatic fever and pericarditis in 1890, and rheumatic fever again in 1892. She is delicate looking, small for her age; she becomes short of breath on the slightest exertion. Her pulse (92) is regular in force and frequency; the artery is small, and not felt between the beats; the wave is short and small and is very easily compressible. There is very marked bulging of the left chest below the second rib, and of the lower sternum; the apex beat is in the sixth space two inches below and one inch outside the nipple; it is a powerful thrust. Its position does not alter on deep inspiration or on her turning on to either side. There is systolic retraction in the third and fourth left spaces, also in the epigastric region, and in the fifth and sixth right spaces for one and a half inches from the

Digitized by Google

sternum. There is well marked pulsation in the fifth and sixth left spaces, and the ribs are lifted. In the left back there is slight systolic retraction of the eleventh and twelth ribs and the region just below. There is no retraction in the right back. The cardiac dulness is in the second space for an inch, in the third space from the mid-sternum to the nipple line, in the fourth space from one inch to the right of the sternum to one inch outside the left nipple, and in the fifth and sixth spaces from one and a half inches to the right of the sternum to one inch outside the left nipple. On deep inspiration the dulness disappears from the second space, but the rest of the area remains. At the apex are heard a short loud first sound, a loud, rough systolic murmur, and an indistinct reduplicated second sound. The systolic murmur is conducted round to the back. Over the tricuspid area a first sound, a blowing systolic murmur, and a slightly reduplicated second sound, are audible. At the pulmonary cartilage there are heard a first sound, a rough systolic murmur, and an accentuated and reduplicated second sound. At the aortic cartilage a first sound, a soft systolic murmur, and a second sound are heard. The liver extends nearly three fingers' breadth below the costal margin. The epigastrium is a little drawn in during inspiration, and the rest of the abdomen moves only very slightly in respiration. The lungs are normal, with good resonance and good breath sounds at both bases.

Of these cases the first is one of aortic disease of rheumatic origin, and the others of mitral regurgitation, with a variable amount of stenosis. In Cases 1, 2 and 4 there is evidence of adhesion of the pericardium to the chest wall as well, but in Case 3 the heart moves freely under the ribs, and the lung expands well over it, so that the sign is much more important, as being the only clear evidence that the pericardium is adherent. This sign has long been pointed out by Sir William Broadbent in the wards of St. Mary's Hospital, but, so far as I have heard, has not had sufficient importance attached to it elsewhere. Adherent pericardium has frequently such a serious influence on the course of valvular disease, that any aid towards the diagnosis seems worthy of attention.

Brook-street, Grosvenor-square, W.

THE NATURAL HISTORY OF HARDWAR FAIR CHOLERA OUTBREAKS.

BY SURGEON-CAPTAIN H. HERBERT, F.R.C.S. ENG.

BEFORE 1892 observation had definitely associated the outbreak of cholera at Hardwar with but one condition—the overcrowding at Kumbh fairs. The only two epidemics of the thirty-four years—1858 to 91[1]—had fallen on two of the three Kumbh years of that period, and these were the only two occasions on which the crush was especially remarkable.[2] The estimated attendance of pilgrims in 1867 was 1,250,000, and in 1879 500,000 or 600,000.[3] At the third Kumbh Mela, 1891, the number of pilgrims—269,345—was scarcely larger than at the Adh Kumbh of 1885, where it was 262,621. There can be little doubt that the holy water drunk at, and carried away from, these gatherings constitutes the only possible means of such immediate and general spread of the cholera poison as was seen in 1867,[4] for example. That is to say, the excessive crowding of bathers at the two greater Kumbh Melas must be regarded as having in some way helped in rendering the water of the Sacred Pool or of the Bhun Ghora tank, or of both, an efficient means of cholera diffusion. Obviously another factor—reduction in quantity of the sacred water—may, as far as the fouling of the water is concerned, have the same result as increase in the number of bathers. This is what happened in the big cholera year 1892. It was one of the driest seasons on record in Northern India. "In the submontane tracts many of the streams were dried up, and the water level in the tanks and wells was much lower than usual."[5] The table[6] here introduced shows that the river was lower in 1892 than in any other of the available series of years[7]; and the deficit at the sacred bathing Ghât was in this year rendered extreme by change in the channel of the river.

Volume of the Ganges at Hardwar in cubic feet per second at the time of the principal annual fair.

Year	Volume	Year	Volume
1881	8000	1888	7000
1882	7000	1889	12000
1883	7000	1890	5500
1884	7000	1891	9000
1885	10000	1892	5000
1886	12000	1893	11000
1887	6000	1894	11000

Though only 70,000[8] people had assembled, yet "it was impossible, however, to keep the water in the bathing-pool so fresh as on the former occasion (1891, Kumbh Mela, 269,000 pilgrims) on account of the smaller volume of water in the river and the direct obstruction to its flow in the sacred pool by recently-formed obstacles and foreshores."[9] "The section of the river channel varies considerably from year to year under the action of the annual floods."[10] Unfortunately, this introduces such an element of uncertainty, that although the sacred pool was fouler in 1892 than at the Kumbh Mela of 1891,[11] we cannot be perfectly certain that it was fouler than in other years, such as might have been characterised by only ordinary accumulation of pilgrims and only moderate drought. The evidence is suggestive only. Though it is possible, it is far from proved that the want of water in 1892 was sufficient to raise the foulness of the pool (and tank?[12]) to a level comparable with that of 1867 and 1879, and above that of all intervening years. Of the other cholera years, 1879 was characterised by moderate drought;[13] and the great mela of 1867 fell on a season at least as dry as ordinary.[14] The exemption from cholera attack of the last Kumbh Mela, 1891, was ascribed[15] to the very elaborate sanitary arrangements for the first time in force; but the evidence is very strong that it was due rather to a severe and prolonged winter season. The complete inefficiency of the sanitary arrangements was well shown by the cholera outbreak in the following year.[16] There were no extraordinary sanitary precautions in 1885, when the number of pilgrims was almost the same as in 1891; yet cholera did not break out. The winter was severe,[17] as in 1891, and the river consequently high. (See table.) And there have been other Kumbh and Adh Kumbh years—e.g., 1855 1861, 1873, with neither special precautions nor cholera. It is now fairly

[1] Epidemics spread from the fairs of 1857 and of 1892.

[2] Figures for the Adh Kumbh fairs of 1861 and 1873 are not available; they may safely be taken as very much less than at the two Kumbh Melas mentioned.

[3] 500,000: Government of India Sanitary Report for 1892, p. 139; 600,000: Government of India Sanitary Report for 1879, p. 124.

[4] "The simultaneous outbreak of cholera on the evening of April 12th in every section of the Hardwar encampment is a phenomenon of great interest. ..... We find a great multitude, which on April 11th was so little tainted with cholera as to be believed to be free from it, thoroughly contaminated in all its parts on the 12th."—Sanitary Administration Report for the Punjab for 1867.

[5] Government of India Sanitary Report for 1892, p. 141.

[6] This table was very kindly supplied by Mr. Bhordon, Under-Secretary to the Government Irrigation Department North West Province and Oudh. He states that the calculations are only very roughly approximate; the volumes given are too low for years of high discharge, i.e., wherever 7,000 cubic feet per second was exceeded. The table includes all the available years.

[7] The variation in the volume of the river is quite small compared with the variation in the number of pilgrims in different years. But it must be borne in mind that the effect of a small change in the level of a river is much exaggerated in its shallower portions.

[8] Surgeon-Colonel Hutcheson, late Sanitary Commissioner to the North-west Provinces and Oudh, tells me that this number is about half of the average accumulation actually present at the height of an ordinary annual fair.

[9] Government of India Sanitary Report for 1892, p. 140.

[10] Mr. Bhordon.

[11] In 1891 the river was full, probably more so than is indicated in the table. "The cold weather was characterised ..... by excessive snowfall in the Himalayas" (India Weather Review Annual Summary, 1891, p. 476). "The cold weather rainfall was the heaviest on record in many parts of Upper India" (India Weather Review Annual Summary, 1892, p. 529).

[12] The construction of a syphon bringing fresh water to the Bhun Ghora tank in 1891 renders its condition in 1892 not readily comparable with that of earlier years.

[13] "The cold weather of 1878-79 was remarkably free from storms in Northern India, and the rainfall of the period was hence considerably below the normal."—Indian Meteorological Memoirs, vol. iv., part viii., p. 580.

[14] The total rainfall at the nearest meteorological station, Roorkee, seventeen miles away, of the first four months of 1867 was practically normal in amount—viz., 4·05 inches; on the hills it was below normal for this period judging from the Naini Tal record, 11·90 inches (average over 17 inches).

[15] Brit. Med. Jour., 1894, vol i., p. 363.

[16] "The sanitary arrangements at the fair (1892) were those which proved so successful in 1891; it was impossible, however, to keep the water in the bathing pool so fresh."—Government of India Sanitary Report for 1892, p. 140.

[17] "The cold weather of 1885 was ..... unusually severe."—Indian Meteorological Memoirs, vol. iv., Part VIII., p. 661.

Digitized by Google

well recognised that the essential sanitary requirement for the prevention of cholera spread here is a very free supply of fresh water, especially at the most crowded Melas, in very dry years, and when the disease is unusually prevalent elsewhere in India.

There was, however, another climatic feature which almost certainly helped in the development of the cholera of 1892. It was not only one of the driest, it was one of the hottest seasons on record.[18] It is significant that cholera broke out on March 22nd, and that the period, 21st to 27th, was the hottest portion of the hottest March on record.[19] Yet this does not mean very much after all, for the fairs have commonly lasted till April 12th, on which date the air temperature in other years must often have been as high as on March 22nd, 1892. On the other hand, it is readily conceivable that the unusually powerful heat rays may have worked to great advantage on the slow and shallow current of the sacred pool in 1892. In one of the other cholera years (1867) the weather appears to have been cooler than ordinary at the time of the outbreak (April); but in 1879 the mean air temperature at Roorkee for the month of April was 3° above the average.[20] Besides 1892 there have been only two Aprils (1875 and 1880) at all hotter than this. On the whole the temperature factor in the origin of the Hardwar cholera outbreaks appears to be of decidedly secondary importance to those affecting the cleanliness of the water.

I have left till last an important consideration—that of the varying prevalence of cholera at the time of the fair among the general population of India, whence the pilgrims are drawn. The cholera mortality of March, 1892, was the highest on record for that month;[21] it was specially high in Bengal. For 1867 the records are incomplete, but it is known that the disease was widely diffused in the country about Hardwar for months before the great Mela.[22] In the early part of 1879 cholera mortality was distinctly less than ordinary.[23] It is noteworthy that the spread from Hardwar in this year was very much milder than in the other two epidemic years. Excessive general prevalence at the time of the great fair must mean an increased introduction, or at least a greater certainty of introduction,[24] of the virus into the sacred water at Hardwar. The same thing is brought about also by the increase in the proportion of bathers, absolute or relative, which has been already discussed. And the question arises whether this may not explain in some measure the origin of epidemics here. But if so it must be in quite small measure, for nothing but the local reproduction of the organism will suffice to explain its wonderfully rapid general diffusion here. And in the laboratory the growth of a microbe depends much more on the character of the culture medium and on the original quality of the organism than on the quantity sown. Excessive prevalence elsewhere means not only increased chances of planting the microbe at Hardwar; it means the sowing of an unusually active organism, one more likely to thrive and multiply. In this way it may increase the tendency to outbreaks at Hardwar. While the effect of excessive crowding of bathers may also be explained in another way, the greater fouling of the water may render it an exceptionally favourable culture material.[25] There is substantial evidence[26] that cholera mortality in India increases with the shrinkage of tanks and other surface water-supplies; and the water of the tanks as it runs low has the same fouling influences at work in minor degree (the stirring up of the mud from the bottom and the direct pollution by the washing of clothes and bathing of the people) seen superlatively at the great fairs. And the suitability of liquid mud for cholera growth is possibly seen also in the enormous mortality attained in Berar when the great thirst of the black cotton soil is appeased by heavy rains, and when the whole country is "converted into a deep, tenacious mud." The vast importance of the culture material at Hardwar is seen in the fact that the cholera which spreads from the fairs is not that which is carried to them. Developing under special conditions in a place where the disease naturally has but a feeble existence,[27] the virus acquires powers of resistance well in advance of those possessed by ordinary Indian cholera. The new growth spreads rapidly and certainly over country where cholera is comparatively seldom seen,[28] and is credited with having been the origin of a European pandemic.[29] The influence of the condition of the culture medium is seen also in the fact that cholera may often be carried to the fairs and fail to spread there.[30] That the spread depends on the quality of the specialised local product rather than on its quantity is suggested also by the observation that the result in 1892 from the dispersal of 70,000 pilgrims was at least similar in magnitude[31] to that in 1867 from the scattering of probably a million people;[32] and Surgeon-General Cunningham, in his report on the epidemic of 1879,[33] notes that there was "no relation between the number of pilgrims and the extent of the disease in different districts." To sum up, there is substantial evidence to support the following suggestions: (1) the fouling of the sacred water by exceptionally large proportion of bathers to the quantity of water available may render it a very favourable medium for cholera development, and so determine the origin of far-reaching epidemics; while (2) the growth of the organism at Hardwar may be assisted by unusually hot weather; (3) virulent cholera elsewhere in India being effective rather in the character than in the quantity of the virus carried to Hardwar.

Bombay.

[18] "Higher day temperatures were noted in March, 1892, over the whole of the interior of India than have been observed during the previous twenty-five years, and the month is hence the hottest March on record."—Government of India Monthly Weather Review, March, 1892, p. 82. The highest temperature registered at Roorkee was 102·2° F., just one degree higher than the highest recorded in March of any other year.

[19] I know of no evidence to show that heat in India, however excessive, is ever in itself other than stimulant to cholera development.

[20] Monthly mean air temperatures have been recorded at Roorkee since 1866. The variations from average of the three cholera years are:—1867: March (about) + 0·6°; April (about) − 2·2°. 1879: March − 1·1°; April + 3°. 1892: March + 1·7°; April + 5·1°.

[21] The total cholera mortality of British India in March, 1892, was 46,089, the next highest record being in 1891—viz., 33,986,—the average for the fifteen years 1879-93 being 18,066. Out of the total of 46,089 deaths 31,235 happened in Bengal.

[22] See Bellew's "History of Cholera in India," p. 425.

[23] The mortality for March was 11,800, for April 29,324, the average for the fifteen years 1879-93 being 36,980.

[24] The great fair occurs near the height of the Bengal cholera season and when the mortality is rapidly on the increase in other directions, so that seldom can the disease fail entirely to be carried to these gatherings.

[25] The bathing pool at the Kumbh Mela in 1891 is thus described: "As the bathing went on the clear stream became a muddy one, and the water collected from any part of it smelt in a few hours offensively, and the micro-organisms developed from it were legion."—Brit. Med. Jour., 1894, vol. i., p. 361. Of the pool in 1867 it is said: "The water within this space was during the whole time thick and dirty, partly from the ashes of the dead brought by surviving relatives to be deposited in the waters of the river-god, and partly from the washing of the clothes and bodies of the bathers."—Government of India Sanitary Report for 1867.

[26] Indian Medical Gazette, 1894, p. 329 et seq.

[27] The average annual cholera mortality of twenty-seven years in the Saharanpur District, in which Hardwar is situate, is only 0·25 per 1000.

[28] Each of these epidemics spread rapidly over the Punjab (including its most immune tracts), Sind, and Cashmere.

[29] Macnamara in Davidson's Hygiene and Diseases of Warm Climates.

[30] Isolated cases of cholera are not uncommon at the fairs; the vibrio was detected in the water of the sacred pool in 1891; and in 1872 there was a localised outbreak confined to a single band of pilgrims who left their mark on the places they passed through.

[31] The mortality figures of the two years are not strictly comparable, owing to the imperfect registration of the earlier year.

[32] The estimate of the number present on the great bathing day made at the time is nearly as large as that of the total attendance of the whole period of the fair (see Bellew's History of Cholera in India, p. 518).

ON VAGINAL HYSTERECTOMY.

BY F. A. PURCELL, M.D., M.CH. EDIN.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON.

THE three cases I am about to record are examples of a large class of cases of malignant disease of the os and neck, or lower third section of the organ, that come under observation, in which a mass of cauliflower epithelomatous growth occupies the cavity of the vagina and discharges a foul and copious sanguineo-purulent fluid, at times a flooding supervening, all tending to lower the patient's general health and strength. The mass of growth may either press on to the rectum, causing pain in the back and hips and difficulty in relieving the bowels, or it may press anteriorly on to the bladder, giving rise to the troubles suffered in consequence and being most distressing to the patient. The patient will present a pale, exsanguinated, and anxious look, and there are many who, if they think that they have not passed the time of the menopause, will attribute much of their pains and discharges to its

Digitized by Google

cause; others, in whom the periods are still maintained, will perhaps seek advice sooner for the discharge complained of; but how numerous are the women, married or unmarried, whose attention is called to their unfortunate condition for the first time "then" by the examining surgeon or by a casual examination by their own medical man, shortly before being sent to a specialist or recommended to go to some hospital for further advice. It is not unusual to find a woman really ignorant of her state when the malady has reached the stage of deep excavation of the uterus and infiltration along the broad ligaments, with fixation of the organ from malignant disease, rendering her condition such that non-surgical interference is the only course to be advised, and although it may seem marvellous that such a state of things should exist unbeknown to the patient, yet such is the fact. It is in these border-line cases, so frequently met with, that it becomes a very serious question as to which is the best course of treatment to advise. In many instances I would most strenuously recommend that the patient be severely left alone so far as operative interference is concerned, only alleviation of the suffering being attempted by the exhibition of drugs; the vagina should be kept as sweet as possible by medicated douches or simple irrigation, and attention should be paid to the bowels, the patient being put in the best condition to cope with the advance of the disease, until death releases her from her sufferings. When operative interference suggests itself the question arises, What operation will best meet the case? and this will be answered by the condition found on examination. The first consideration is the amount of mobility of the uterus. If it is not mobile, it may be assumed that the disease has already extended or infiltrated along either or both of the broad ligaments; these should be critically examined, which is more easily done through the rectum, and possibly under an anæsthetic if the patient be nervous or cannot bear slight pain. If the broad ligaments are free from extension of the disease, then supra-vaginal amputation will suggest itself. I have treated cases by chloride of zinc paste; this treatment cannot be carried out in this class of cases, because invariably when supra-vaginal amputation is performed the peritoneum is of a necessity opened, which in itself would debar the preparing and excavating of a cavity in the fundus for the insertion of the chloride of zinc plug of cotton wool. This treatment must be reserved for those cases where the disease originated in the neck or fundus of the uterus, and in which the disease has not eroded the os, and where the mucous membrane of the vagina is intact. In all cases, before deciding on any operative interference, it is necessary to examine the vaginal mucous membrane, for if the disease has spread to the mucous membrane the deeper submucous tissues have already become infected and recurrence of the disease is bound to follow, and it is a contra-indication to removal by partial or total methods. In these border-line cases, when the growth is found to occupy the vagina the finger may be able to pass round the mass, and though the growth is found to emanate from either one lip of the os, or usually, as it does, from the neck, it may be observed that the fornices of the vagina and the mucous membrane around are free and therefore present a favourable prognosis, and operation may be justifiable. Before, then, deciding on total removal it is well to postpone its being undertaken until all the steps of supra-vaginal amputation have been performed and the uterus has been divided off at the internal os. Of a necessity the peritoneum will have been opened both behind and before, and the bladder stripped up. The portion then removed I have invariably handed over to our pathologist, Mr. Plimmer, or, if he was not present, to one of my colleagues, to examine. If it should turn out that the upper surface seems to be normal and free from disease, it is assumed that the stump of the uterus is also free and that we have got beyond the disease. In this case one stops short of doing more, but in case there should be even the smallest doubt of disease showing on the cut surface there must be no hesitation in then completing the entire removal of the organ. During the removal of the part by supra-vaginal amputation the lower uterine arteries of a necessity are divided and clamped and afterwards tied, which is the first stage towards total extirpation. If proceeding to total removal the fundus of the uterus is seized, usually on its anterior surface, with a pair or more of vulsellum forceps, and by drawing on the fundus anteflexion is produced and the fundus is coaxed down and delivered to view; it may so happen that retroflexion may be the more easy to do, when the posterior surface of the uterus is to be seized and the uterus is coaxed down in the posterior fornix. One cannot be wedded to either method, but should act according to the most expeditious plan that presents itself. The tube, round ligament, and remainder of the broad ligament on one side are transfixed with silk ligatures and tied; one end of the ligature is allowed to remain long and the other end is cut short, a pair of pressure forceps being applied near the ligature on the uterine side before the part is divided off. The second side is treated in the same way, when the uterus, being freed, is removed. The parts are douched out with warm boric acid solution, and any bleeding point that may show itself is caught and tied; the parts are then dried and the toilet is completed. I usually insert a glass drainage-tube and around this pack the vagina with a long strip of iodoform gauze, and after a wash-up if necessary the patient is removed to her bed. The position during operation is the lithotomy one, maintained by means of Clover's crutch, the buttocks being brought well over the edge of the table. Ether is employed as the anæsthetic; the time occupied is usually from forty to forty-five minutes. If the patient has passed the time of the menopause, although the ovaries may present themselves, I have in most of my cases allowed them to remain; I have observed that they form a buffer to the coming down of the bowel, and therefore it is advantageous to leave them. If in a younger woman I could be persuaded that they, if left, would cause no ulterior inconvenience I would be inclined to leave them with the same object as I have stated; however, if I have found an ovary cystic and much enlarged, I have removed it. After operation I usually give an anodyne, and guard during the first twelve hours against sickness from the anæsthetic or threatened collapse by giving, if necessary, some brandy in warm water. On the morning of the third day, or at least twenty-four hours after the operation, the vaginal packing and drainage-tube are removed, the parts are then irrigated with a warm solution of boric acid, and the vagina glass drain is reinstated and gauze packing plugged in, but not so firmly as before. At the end of the next twenty-four hours, if no discharge be noticed on the perineal pad, the glass drain may be altogether withdrawn and a strip of iodoform gauze alone inserted. About the fourth or fifth day possibly a discharge of pus will be noticed on the perineal pad. I say possibly, for in some cases pus is not formed; in case it is, I insert a red-rubber large-sized drain. Douching is continued night and morning. The ligatures come away between the tenth and twentieth days. A soft rubber catheter is kept in the bladder, having been inserted at the time of the operation and utilised as long as any dressings are applied. About the morning of the third day I generally give a saline aperient, and if the abdomen should be at all tympanitic, or the patient should suffer from flatulency, turpentine fomentations are applied, and possibly a turpentine enema is administered. The most critical period is about the fourth day, and in my experience if that day is passed favourably the patient makes an uninterrupted recovery, after which she must run her chance of recurrence. The risk of these operations, especially in such far advanced cases, is danger of damaging the bladder, as disease encroaches on its wall and weakens it, so that a rent is apt to be made into the viscus. In such a mishap it is necessary to keep the catheter in the bladder and await the healing and closing in of the vault of the vagina, when the fistula will be found in the vaginal cavity and may be healed by means of the cautery or nitrate of silver; these means failing, then only it will have to be treated by the usual operation for a vesico-vaginal fistula. We have tried vaginal bags to catch the urine when the fistula cannot be dealt with. The risk of damage to the ureters I only mention in order that the accident may be avoided.

In Dr. James Braithwaite's paper on the Micro-organism of Cancer, published in THE LANCET of June 29th, 1895, he states that out of a very large Jewish population in Leeds, in not one Jewess has he ever met with cancer of the genital organs, whereas it is extremely common amongst the Christian women, the inference being (assuming the existence of a micro-organism as the cause of cancer) that it is introduced or not introduced by the husband, according to his faith. On microscopic examination of the secretion frequently contained within the prepuce some spores were found, and also two minute loops of mycelium identical in appearance with that which he describes. If it should prove (after Dr. Braithwaite) from this discovery of his, that this micro-organism is the real explanation of the cause of malignant growth, then he sums up in No. 3 answer to the question he lays down—viz., It is possible

Digitized by Google

that we may have to return to a certain Mosaic rite in order to save our wives from uterine cancer, unless the daily use of soap will do away with this necessity. I for one tender my greatest appreciation and thanks to Dr. Braithwaite for his very suggestive paper. It will be seen that in the first and third of these cases recurrence had taken place after a previous operation where removal of the os through the neck had been performed, and that the second was a primary case.

CASE 1.—A married woman aged fifty, mother of two children, had had good confinements; eight months previously she was first troubled with a white discharge from the vagina. In September, 1894, she was admitted into the Chelsea Hospital for Women under the care of Dr. Duncan, who operated and amputated the os. She was admitted into the Cancer Hospital on Dec. 3rd, 1894, and stated that since the previous operation she had had a continual bloody discharge. On examination the vagina was found to be long, and recurrence of malignant disease of the stump extending up the uterine canal was felt. The mucous membrane of the vagina posteriorly was diseased. The patient was of a more or less happy disposition, and was fairly well nourished. On the 8th I performed vaginal hysterectomy. The mucous membrane was incised well clear of the disease. Some of the ligatures came away on the tenth day after operation, and the last ligature on the twenty-second day; she made a good recovery and was discharged. I saw her six months afterwards and found a slight recurrence in the extreme vault. This I treated with iodine, what I call an iodine bath—that is, fixing the speculum firmly applied against the vault and then pouring sufficient liniment iodi down the speculum to cover the disease, which takes about half an ounce, and this is kept in contact for about five minutes and then run off and the parts dried. This has been frequently repeated at intervals of a week, and it has certainly done good. This case is an example of recurrence from previous implication of the mucous membrane.

CASE 2.—A married woman aged forty-five years was the mother of nine children, the last one born seven years ago; her labours had been natural. The patient was recommended by Dr. Fitzgerald of Harrow-road, and was admitted to the Cancer Hospital on May 6th, 1895. She had been troubled with a discharge for the previous two months, and had suffered from bearing-down pain and a dragging in the legs. She was always tired and everything seemed a trouble. She was pale and of a placid disposition. On examination the vagina was found to be occupied by a large mass of epitheliomatous disease; the finger was with difficulty got round and the vaginal mucous membrane was felt to be smooth and apparently not infiltrated; high up in the neck anteriorly a boss was felt pressing forward; the uterus was fairly movable. Vaginal hysterectomy was performed on May 11th. The disease was very extensive, and was first removed by working with scissors from before backwards through the neck; there was no bleeding. The parts were then freely douched out with carbolic solution and the further steps for total removal followed; the ovaries were allowed to remain. The specimen when opened showed extensive disease and had near the fundus a cancerous nodule. The patient made a good recovery.

CASE 3.—The patient had been a widow for twelve years and was mother of six children. She was admitted to the Cancer Hospital on April 25th, 1895, and complained of a purulent discharge, which was sometimes bloody. On examination the vagina was found to be occupied by a fungating cauliflower mass; the vaginal walls were not implicated, the fornices were high up, the uterus was movable, and the broad ligaments were free. Eight years previously she had been admitted into Middlesex Hospital, where the neck was amputated for disease of the os. On May 11th I performed vaginal hysterectomy. The diseased mass was first removed, and some difficulty was experienced in incising the mucous membrane. The operation of total removal was completed; the ovaries were left. Convalescence was somewhat protracted, but the patient made a good recovery and was discharged.

These three specimens I had the pleasure of exhibiting at the British Gynæcological Society's meeting on the 11th inst.

Manchester-square, W.

THE Gaskell medal and prize in mental and nervous diseases at the Royal Bethlem Hospital has been awarded after examination to Mr. George W. F. Macnaughton, M.B., C.M. Edin.

A FEW WORDS ON SOME COMMON FORMS OF REFLEXES OF NASAL ORIGIN.[1]

BY ADOLPH BRONNER M.D. HEIDL.,
SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL, AND LARYNGOLOGIST TO THE BRADFORD INFIRMARY.

A GREAT deal has been written on nasal reflexes. As far back as 1565 we find that Botallus records cases in which the scent of flowers brought on pain in the head and difficulty in breathing. Van Helmont in 1577 describes some typical cases of hay fever. Bostock[2] was himself subject to hay fever. No great importance was, however, attached to this subject until 1871, when Voltolini[3] published several cases of asthma in which nasal polypi were found, and where the removal of the polypi cured the asthma. Fraenkel, Lennox Browne, and others soon followed suit, and proved that the cases recorded by Voltolini were by no means uncommon. In 1881 Hack of Freiburg published his well-known book on Nasal Reflexes,[4] in which he attempts to prove that not only asthma, but many other similar symptoms can be caused by intra-nasal irritation. He divides these reflex symptoms into four classes—(1) spastic, (2) sensory, (3) vaso-motor, and (4) secretory. Numerous cases are recorded of asthma, hay fever, megrim, supra-orbital neuralgia, swelling and redness of the nose, vertigo, epileptiform attacks, &c., which had been cured by intra-nasal treatment. Hack's theory was that these reflex symptoms were due to irritation of the terminal fibres of the fifth nerve, which irritation was caused by the swelling of the cavernous tissue of the mucous membrane of the turbinated bones, especially the anterior part of the lower turbinated bones. His idea was to remove this cavernous tissue by the galvano-cautery, and then any irritation of the nerves would be impossible. Experience, however, soon proved that this theory could not be quite correct. Then, in the first place, the destruction of the cavernous tissue did not always prevent a recurrence of the reflex symptoms. Secondly, in many cases artificial irritation of this part of the mucous membrane brought on the reflexes without causing any swelling of the cavernous tissue. Hack himself, in 1885,[5] practically abandons his theory. In 1882 Fraenkel, J. Mackenzie, and others opposed Hack's theory, and stated that the reflexes were caused by some irritation of the terminal fibres of the fifth nerve, due to changes in the mucous membrane of the turbinated bones or septum, but that the swelling of the cavernous tissue need not have anything whatever to do with the irritation. Lublinski,[6] Heymann, and others think that the reflexes cannot occur unless there is a predisposing neurotic temperament. Boecker repudiates the reflex theory altogether, and states that the intra-nasal changes are mostly incidental complications or that they themselves form part of the symptoms of a central neurosis. In speaking of hay fever Morell Mackenzie[7] said: "The causes of hay fever may be conveniently divided into the predisposing and the exciting. Race, temperament, occupation, education, mode of life, sex, heredity, and age are some of the predisposing causes." Mackenzie did not seem to believe in local treatment for the cure of hay fever. Everyday experience, however, proves that many cases of hay fever, though of course by no means all, are due to a reflex action originating in the nose. Woakes[8] says that the reflexes are—(1) symptoms due to excitation of the sensory-motor nerve elements of the region implicated; and (2) those which involve vaso-motor nerves of the sympathetic system in relationship with the affected structures. As regards asthma, he thinks that it is due to irritation of or pressure on the nerve of Cotunnius, where it crosses the osseous part of the nasal septum. I myself am of opinion that we ought to divide nasal reflexes into two classes: (1) those cases in which there is some local irritation of the terminal fibres of the fifth nerve, due to nasal polypus, pressure of the mucous membrane of the turbinated bones on

the septum, local atrophy or hypertrophy of the mucous membrane of the turbinated bones or of the septum, disease of the turbinated bones themselves, foreign body in the nose, &c.; and (2) those cases in which the nasal changes are not primary, but are themselves the outcome of some central neurosis. In the latter class of cases the local treatment of the nares, such as the use of the galvano-cautery, stops the reflex symptoms, not because it removes the irritation, but because it acts as a powerful counter-irritant. McBride[9] advocates this latter theory.

There can be no doubt that intra-nasal irritation can and frequently does give rise to reflex symptoms, such as asthma, hay fever, megrim, vertigo, and epileptiform attacks, but it does not by any means follow that it is always the cause of these symptoms. We know that in many cases gastric or uterine irritation can give rise to similar symptoms. It follows, however, that it is absolutely necessary that in all these and similar cases the nares and post-nasal space should be carefully and thoroughly examined. If we can find any obstruction to the free passage of air, such as hypertrophy of the mucous membrane, polypi, deviation of the septum, post-nasal growths, &c., or any changes in the mucous membrane (hypertrophy or polypoid degeneration, &c.), these must be treated and cured. Even if the treatment does not remove the symptoms it cannot do the patients any harm, but must be of benefit in other respects. I need not refer to the connexion between these diseases and those of the ear and throat, and how any nasal obstruction prevents the normal development of the lungs and arrests the growth of the body and of the mind. Innumerable cases of asthma, hay fever, megrim, and supra-orbital neuralgia have been cured by intra-nasal treatment, and a large number have been recorded. I can call to mind a series of typical cases of asthma, hay fever, sneezing, megrim, and redness and swelling of the nose, which have come under my notice, and which have been cured in most cases by removal of nasal polypi or by the application of the galvano-cautery to the diseased mucous membrane of the lower turbinated bones.

Bradford.

A CASE OF POST-PARTUM TUBO-OVARIAN ABSCESS IN A PECULIAR POSITION.

BY FREDERICK EDGE, M.D. LOND., F.R.C.S. ENG.

THE patient was a woman twenty-one years of age, of slight but active frame, and generally sound. Four months previously she was confined of her firstborn child, and she informed me that she had had a severe confinement. There was no special cause of obstruction or hæmorrhage, neither was laceration to any degree of the parturient canal noticed. After the birth of the child the patient did not gain strength and recover quickly, but had a severe illness with fever, pain in the left side of the pelvis and down the left leg, and a mass in the left side. When admitted there was no fever, but the pulse was from 90 to 100. She complained of pain in the left side and general debility. The pain was much increased if she was up for a short time. On examination of the abdomen a prominence in the iliac fossa was seen; this could be felt as a firm, rounded, crescentic mass, in which fluctuation was doubtful, and it was dull on percussion. Per vaginam the uterus was felt to be fixed to a mass on the left side which spread to the pelvic wall. Bimanually the uterus could be felt distinctly, and a boundary marking it from the lateral mass, but not separating it by any division, was perceived by a difference in consistence and roughness of outline. By the sound the uterine cavity was found slightly enlarged and dilated, but not more than one would find often at the same period after labour. The mass did not push down the posterior fornix, and the posterior wall of the uterus was free. As there were no urgent symptoms the patient was kept at perfect rest for six weeks, and her bowels were constantly emptied by saline aperients; alteratives and absorptives, counter-irritants, with ichthyol-glycerine applications in the vagina and hot douches and enemata, were all carefully tested, and their conjoint action was accompanied by a gradual lessening of the swelling, and would, perhaps, have attended its disappearance if the patient could have been rested indefinitely. At the end of six weeks she was allowed up for a couple of hours, and she next morning noticed a great increase in the size of the mass and in the pain and discomfort. From the shape of the swelling, its position, the absence of fever, and its history, I diagnosed the condition as one of pyosalpinx with cellulitis of the broad ligament, and as I could not keep the patient on her back indefinitely, she being a labouring woman, I thought it would be good practice to explore, and, if found, to remove the pyosalpinx. On opening the abdomen great adhesions were separated, and then for some time I could not make out the condition of the parts, or what I had to deal with, or what I was going to do. The pouch of Douglas was free, which rather put me off pyosalpinx, and I was inclined to think that I had to deal with a simple plastic cellulitis of the left broad ligament. The omentum was in a column or rolled bundle, and was adherent widely in the left iliac fossa, which is uncommon in simple cellulitis. I tried to separate its adhesions, but failed, as the bleeding became severe. I then tied the whole omental bundle in two places, cutting between. It was evident now that the tube and ovary were implicated, and the resulting mass, which contained a fluctuating cyst of Tangerine orange size, was fixed high on the left pelvic wall and in the left iliac fossa, where the omentum had covered it and adhered to it and the parietal peritoneum. The tube and ovary and broad ligament with omentum were removed, together with some parietal peritoneum which was torn off. The attachments were tied off in two pedicles, one at the horn of the uterus and the other at the pelvic wall. The separation was very difficult, and the sigmoid flexure, which was intimately adherent, was badly torn, but not sufficiently in any place, so far as was noticed, to require suturing. A Keith glass drainage-tube was used after washing out with Mr. Lawson Tait's apparatus. The patient's pulse and temperature before operation were 90 and 98° F. respectively. There were collapse and great pain, so that an injection of morphia was given (in my own abdominal sections I have only given morphia twice before, and each patient died, so that necessity is great before I use morphia). An enema of one teaspoonful of common salt, half an ounce of brandy, one ounce of milk, and five ounces of water was given three times in the night. On the evening of operation the pulse was 124 and the temperature 98°. The next day the pulse was 140 and the temperature 98·8°. Slight distension was treated by calomel and enemata of soap, turpentine, glycerine, and castor oil. At 9 P.M. the pulse was 152 and the temperature 99·2°. The bowels did not act either with flatus or fæces, and two days afterwards fæcal matter exuded from the abdominal wound freely. As the enemata were irritant they were changed into free irrigation of the rectum with normal saline solution, which, passing upwards, helped to clear the abdominal channel. The patient gradually improved, and although the fæces passed through the abdominal incision alone for three days she felt better. Gradually more passed per anum, and now the fistula is almost closed. She is walking about at present and gaining strength and flesh.

These fistulæ are very chronic, and no doubt the silk ligatures act as setons. The points of interest in this case are to my mind as follows. 1. The absence of fever when the patient was kept resting. This seems to point away from pus in any cellular tissue and is more in accord with pus contained in a cavity lined by mucous membrane or its homologue as an ovarian follicle. 2. The peculiar position of the mass of exudation and adhesions around the cyst containing pus. In these cases of post-partum suppuration of the appendages it must be remembered that the germs have already gained access to these parts often at or before conception from the other side has taken place. They are generally unilateral; hence the tube which is carried up into the level of the iliac fossa during pregnancy, if inflamed, would form adhesions at this level, and after labour the descent of the uterus would tend to drag upon the adhesion and permit leakage, which would excite peritonitis and fix the omentum. A condition similar to this, if not the same, was described by Mr. J. W. Taylor, and he pointed out in certain cases the difficulty of making out such a tube-sac owing to its position. 3. The frequence of post-partum suppuration in the tubes and ovaries. When we reflect on the possibilities which the corpus luteum of the ovary, a mass of lowly organised clot, offers, the widely patent tube in which ciliated epithelium must be merely side fringes at these times, and the uterine and vaginal states, we cannot be surprised at this. The abscess usually distends the ovary, but the tube mouth is spread on the ovary, and if detached the

[9] Brit. Med. Jour., Jan. 22nd, 1887.

Digitized by Google

abscess ruptures, as did the abscess cyst in this case. 4. The passage of fæces and flatus through the fistula alone for three days. This only shows the extent of the deficiency in the bowel wall, and perhaps the collapse of the distal bowel. This exercised my mind somewhat as to treatment. At first I put a glass, then a thick rubber, drainage-tube into the rectum, thinking to prevent the passage through the fistula by providing a constant escape per anum; but I afterwards removed it because it occurred to me that by keeping the distal bowel always collapsed I might entirely defeat my purpose, since the laceration in the bowel would thus be brought to gape more widely, and thus offer a direct passage into the fistulous track. This is merely theory, but it may be useful to think of these *minutiæ* in certain cases. It may be asked whether the operation has been of use at all, and I can answer that I believe it has, because it has removed a sac of pus from the pelvis. This sac would not have become absorbed quickly (the lessening by treatment was of the surrounding inflammatory exudation and adhesion chiefly). It could not without rupturing an organised cellular wall escape externally, as a cellulitic abscess does, and finally heal after long discharge. If it had subsided for a time so far as to allow conception again to take place there would have been trouble during pregnancy and every possibility of rupture and fatal peritonitis at the confinement. Should the fistula not close within six months I shall, with the patient's consent, reopen and remove the silk ligatures if possible. At such a depth I should not try to find the opening in the bowel and close it, unless, indeed, I am mistaken as to the remoteness of the fistula. The fistula has now healed up (July, 1895).

ST. THOMAS'S HOSPITAL.

THE SURGICAL REPORT OF A CASE OF JACKSONIAN EPILEPSY WITH APHASIA, INTELLECTUAL IMPAIRMENT, AND PARTIAL HEMIPLEGIA, TREATED BY TREPHINING.

(Under the care of Mr. W. ANDERSON.)

IT is difficult to state the nature of the lesion which caused the symptoms in this case, but there can be no doubt as to the benefit which the patient has derived from the operation. It will be interesting to learn the ultimate result of the operation. For the notes of this case we are indebted to Mr. Cuff, late house surgeon.

The patient, a boy aged thirteen, was admitted into Arthur Ward, St. Thomas's Hospital, under the care of Dr. Payne, in September, 1894. He was the fifth and only living child of his mother, whose other infants were stillborn. Shortly after birth he manifested undoubted signs of congenital syphilis, including snuffles and sores on the nates and around the anus, which were treated successfully by mercurial inunctions. Up to the age of ten he was regarded as a bright boy; but from this period his mental and physical evolution came suddenly to a standstill without any apparent cause, and he became silent and morose. A year later he was seized by a fit of tremors and twitching of the mouth, followed by partial loss of speech and shuffling gait. He imperfectly recovered from this and continued to go to school, but six months afterwards he had an epileptic fit. Again an interval of improvement followed; but a few weeks later he suddenly became aphasic, and the defects in his intellect and gait became strongly marked. On admission to hospital he presented the aspect and development of a boy nine or ten years of age. His head appeared to be of good conformation, but his frontal eminences were unduly prominent, and his expression was stupid and rather vicious. The incisors were pegged, but there were no other marks of congenital syphilis. The intellect was gravely impaired; he was childish and irritable in manner, his speech was thick and hurried and usually limited to "Yes" or "No," but he appeared to understand when spoken to. He called things by the wrong names and did not recognise letters, although he could repeat words correctly when he heard the sounds. His legs showed a tendency to involuntary and sustained contraction of the extensor muscles, and in walking he kept the limbs widely separated. The arms were normal. The pupils acted to light and the right was smaller than the left. He improved up to Oct. 12th last, when he was attacked by epileptic fits, three in the day. On the 13th the fits were fourteen in number, and on the 14th as many as twenty. From this time they recurred in numbers of fifteen or twenty every day. During the fit the eyeballs turned to the right, the right arm was slowly raised and pointed forwards, the elbow was extended, the wrist flexed, the thumb flexed and adducted, and the third and fourth digits were bent. The right side of the face, with the right arm and sometimes the right leg, twitched, and the right pupil was dilated. The attack lasted for about two minutes, leaving the boy drowsy, with partial paralysis of the right side of the body. After the fits had set, in the right arm was found to be almost useless, all power of walking was lost, and the intelligence became infantile. After a consultation between Dr. Payne and Mr. Anderson it was decided to trephine over the motor area and explore the condition of the brain and membranes at that point. On Oct. 27th a circle of bone an inch and a half in diameter was removed from a point in front of the lower end of the fissure of Rolando, on the left side, exposing the membranes over the convolution of Broca and the lower parts of the precentral and second frontal gyri. The dura mater was found to be normal in aspect, and on incising this the brain with its arachnoid and pia mater bulged strongly into the wound, and it was noticed that the cerebral pulsations, at first indistinct, quickly assumed their natural character. The arachnoid was somewhat opaque and presented yellowish lines opposite the sulci. A grooved needle passed into the brain tissue in two or three directions revealed no abnormality. The incision in the dura mater was not closed, but the scalp wound was sutured and dressed. On the night of the operation the boy was very quiet, but spoke one or two words when addressed and seemed to be quite conscious of his surroundings. On the 31st the strength of the right arm appeared to have become greatly restored. No fits had occurred since the operation, but his temper was very irritable. The wound healed by first intention. From the time of the operation the patient made unbroken progress. The fits did not return, speech steadily amended and within a few days became fairly connected, the memory for names became stronger, and he was able to tell his own name and to write it, but there was still much to be desired. He recollected recent events vividly, and not only recognised a fellow patient who had just returned from a convalescent home, but mentioned the place from which he came. The irritability of temper subsided, and the power of observation and reasoning power rose daily to a higher plane. The gait became firmer, although in walking the legs were still kept somewhat wide apart, and the arm completely recovered its utility. When discharged on Jan. 6th, 1895, the restoration of his powers was still progressing, but he had not reached the full standard of his age. It was decided to await the course of events. The last report states that he is in good health, free from fits, and from paralytic symptoms, but his intelligence is still incomplete and his education at a standstill.

Remarks by Mr. ANDERSON.—Omitting all comments on the medical aspect of the case, it is sufficient to notice that the good effect of the operation, marked as it was by so rapid and extensive an amendment in the intellectual and motor powers of the boy and by the complete abolition of his epileptiform attacks, followed the mere removal of a portion of bone with a division of the dura mater, which could do little more than diminish intracranial tension and allow a better nutrition of the previously compressed structures. The bulging of the brain into the aperture and the speedy restoration of the normal pulsation immediately after the operation were significant in the same direction. It still remains to be seen whether a second operation over the upper precentral and frontal gyri may not be advisable with a view to influence further the still defective intellectual functions. It is not many years since cerebral surgery, except in cases of traumatic injury, was practically non-existent. It is true that in prehistoric times trephining was practised apparently as a remedial measure and without necessarily killing the subject of the experiment, and the operation was

Digitized by Google

recommended in certain cases by Hippocrates. What were the conditions for which the earliest operations were performed it is impossible to say, but within the historical period it was employed more or less unscientifically by surgeons for head injuries and was sometimes prescribed by the physician in a rather reckless way for internal disease. We are told, for example, that Philip William of Orange was trephined seventeen times for headache by order of his physicians, and as he survived, the fact at least speaks well for the skill and care of the surgeon. And it is interesting to learn that our modern practice was to some extent forestalled over 200 years ago in a book of but little value or importance, published in 1685 by a surgeon named Hugh Ryder, who trephined over the left motor area to relieve "a paralysis of the right arm, head, and tongue" following an injury to the opposite side of the head. A circle of bone was removed on the seventh day, setting free a quantity of black grumous blood, which blood, explains Ryder, "by pressing upon the meninges and sending forth putrid steams had been the occasion of the ill symptoms." The result of the experiment was successful. The method of cerebral localisation adopted in the case now reported was that published by Mr. Anderson and Mr. Makins in THE LANCET of July 13th, 1889. In this, to secure the indications most needed by the surgeon, the fissures of Rolando and Sylvius, it is only necessary to measure a median sagittal line from the glabella at the level of the upper margins of the orbits in front to the occipital protuberance behind, to bisect this and mark the mid-sagittal point. From the latter a tape is run down to the "preauricular" point immediately in front of the tragus at a level with the upper border of the meatus, and a point, the "squamosal," is marked at the junction of the lower and middle thirds of this "frontal line." A third line, the "squamosal line," drawn from the external angular process through the squamosal point gives the line of the fissure of Sylvius, the commencement of which is five-twelfths of the distance between the external angular process and the squamosal point. The fissure of Rolando is now found by marking two points, one half an inch behind the mid-sagittal point above, the other half an inch in front of the squamosal point below, and joining these by a line. The whole process is effected far more rapidly than it is described, and can be completed in two or three minutes with a common tape measure. The advantages that may be claimed for it are rapidity, simplicity, and adaptability to heads of all sizes and shapes. The sole appliance required is a tape measure graduated in inches and lines.

CLAYTON HOSPITAL, WAKEFIELD.

A CASE OF COMPLETE INVERSION OF THE UTERUS; RECOVERY; REMARKS.

(Under the care of Mr. W. STANGER.)

COMPLETE inversion of the uterus after delivery is one of the rarer accidents met with in practice, and constitutes a condition of extreme gravity. The hæmorrhage which accompanies inversion is sometimes sufficient to cause death before help can be given, in other cases it is not a marked symptom, and the greatest danger is from complications. The rarity of this condition is explained by the fact that a combination of special causes is probably required for its production, although undue traction on the cord must be regarded as an important and sometimes as a sufficient one. For the notes of this case we are indebted to Mr. C. Hutley, junior house surgeon.

A patient aged twenty-three, a primipara, was on Feb. 9th sent to the hospital with a note saying that she was suffering from extreme prolapse, pain, and hæmorrhage. The history was as follows. She had been confined on the 5th. The child was born at full time, living and healthy. The patient had had pain and some bleeding since. On the 9th a large mass protruded from the vulva, after which the bleeding and pain increased. From the midwife it was afterwards learned that the labour was somewhat tedious; it was a head presentation. The cord was above the average length and the placenta came away by itself ten minutes after the child. On admission the patient was blanched and rather collapsed. The pulse was fairly good and the temperature was 99·8° F. On examination of the parts a rounded, dark, reddish mass larger than a cricket ball was seen protruding from the vulva, on which the placental site could be distinctly seen. A few small blood-clots were seen on the surface of it. The patient was put under the influence of ether and the inverted uterus was well washed in carbolic lotion (1 in 40) and replaced by Mr. Stanger and Mr. Jones with much difficulty. An intra-uterine douche was then given, and also a hypodermic injection of ergotin. Uterine douches were given twice daily, and vaginal douches every four hours. On Feb. 10th the douches returned quite clear and sweet; the temperature was slightly raised. On the 11th the morning uterine douche returned slightly turbid; on the 12th the douches were quite clear. On the 24th the patient was quite convalescent, being able to get up, and on the 26th she was discharged.

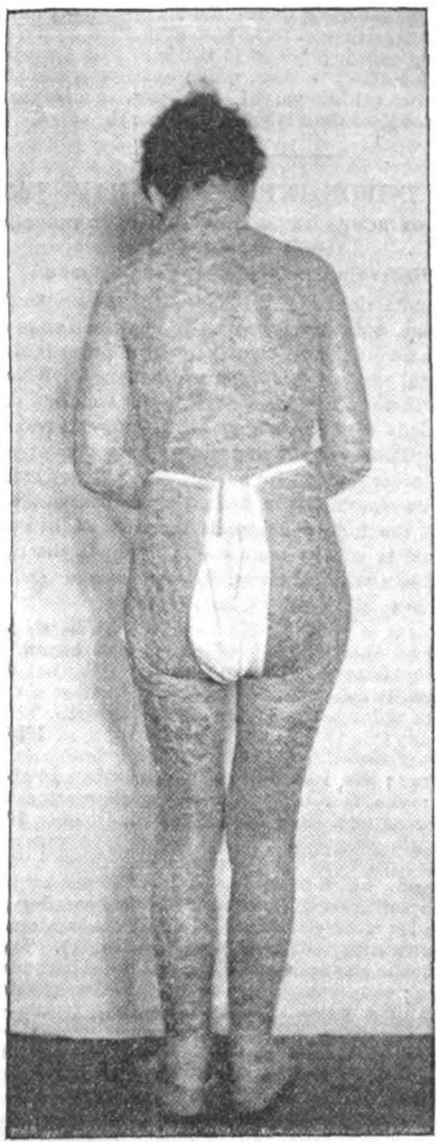
Remarks by Mr. HUTLEY.—The most striking peculiarities in this case are as follows:—1. The patient was a primipara. 2. The fact that the inversion did not show itself till nearly five days after delivery. The patient had pain and bleeding. These symptoms justify one in believing that after delivery there was a partial inversion, which, acting as a foreign body, caused violent contractions of the uterus, and became more and more inverted until it projected from the vulva.

NORTH DEVON INFIRMARY, BARNSTAPLE.

A CASE OF ACUTE GENERAL EXFOLIATIVE DERMATITIS (PITYRIASIS RUBRA).

(Under the care of Mr. WALTER COOPER.)

VON HEBRA described this disease as a specific form of skin eruption, but rarely met with and having a close affinity with psoriasis. Bristowe[1] writes: "Its progress is slow and it is doubtful whether a cure is ever effected. When fully developed there is nothing except the history and progress of the malady to distinguish it from universally diffused psoriasis. Patients suffering from it remain apparently healthy in other respects for a long time; but they ultimately emaciate, become cachectic, and sink from exhaustion." The account of the following case is therefore of considerable interest, and it will be more especially so if the apparent cure becomes a permanent one. For the notes of this case we are indebted to Mr. F. Penny, house surgeon.



The patient, a woman aged twenty-eight, a widow with four children, she being one of a family of eleven, gave a good family history free from skin complaints, but she had been subject to epileptic fits. There was neither history nor evidence of either hereditary or acquired syphilis. Her first attack of any skin trouble was in the summer of 1884, when she had what seemed from her description to have been eczema on both legs; this lasted about two months and then disappeared; she had had somewhat similar attacks every summer or autumn since that time. In October, 1894, she had psoriasis (diagnosis of the medical man who attended her) on the calves of both legs and the flexor surfaces of both forearms, which in the early part of December began to spread, appearing on the trunk and rapidly becoming general, so that on her admission (Jan. 1st, 1895) she was completely covered with a dry scaly eruption (see Fig. 1). The scales varied much in size and were largest on the shins and around the ankles; they were irregular in shape, very thin, non-laminated, of a yellowish-white colour, very easily detachable, separate, never adhering into crusts, and excessively numerous, more than a pint a day being shed, and where shed fresh scales quickly formed. Under the scales the skin was a vivid red, except on the shins and around the ankles, where it was purple; there was no thickening of the cutis vera and no exudation and no puncta were visible to the naked eye. There was at times slight irritability of the skin, though this was never excessive and frequently altogether absent. The scalp was badly affected and the hair came out considerably during combing. (Fig. 2.) Her voice was thick and husky, and there was some congestion of the mucous membrane of the mouth, throat, and larynx. The urine was strongly alkaline, but contained neither albumen nor sugar. The temperature, pulse, and respiration were about normal and varied but little while the patient was under observation. On Jan. 1st the patient was sent to bed, and carefully protected from draughts and from chances of taking a chill. She was allowed a light and nutritious diet; cod-liver oil,

[1] Theory and Practice of Medicine.

Digitized by Google

and a mixture containing potassii iodidum, liquor hydrargyri perchloridi, and decoctum sarsæ compositum were given. Ichthyol and oleum olivæ in equal parts were kept constantly applied by means of bandages to the right arm, while the remainder of the body was enveloped in a pair of combinations soaked in liquor plumbi subacetatis, 2½ oz., with oleum amygdalæ to make one pint. On Jan. 9th much less scaliness was present, especially so about the trunk, and irregular streaks of more healthly-looking skin appeared on the chest, but the legs were not much improved. The medicine ordered on Jan. 1st was changed for an effervescing mixture containing three grains of quinine, the patient being allowed

FIG. 1.

Condition of patient on admission.

ordinary diet. On the 14th the ichthyol application was used for the left leg, but as it caused considerable pain it was given up on the 15th, and the lead and almond oil used for the whole body. Until the 26th the improvement (except on the legs) was most satisfactory, but on that date a few fresh patches were seen on the face and chest, which had become almost clear; these appeared as roseolous blotches, and in about twenty-four hours were covered with fine scales. On the 30th the improvement was very marked, and five minims of liquor arsenicalis were added to the medicine. Very little improvement took place during the next few days, and on Feb. 6th the medicine was changed again to the mixture of Jan. 1st. On Feb. 12th the left leg was still very troublesome, and an application of 2½ per cent. oleate of mercury was used, but as this caused a crop of small pustules it was discontinued. By the 16th in many places the skin had become quite clear, and where the disease still existed very few scales were formed. A lotion of glycerine, zinc oxide, and lime water was then ordered. On March 4th the few small patches of eruption still remaining were dressed with unguentum boracis, and the decoctum sarsæ in the medicine was changed for decoctum cinchonæ. The patient was now

FIG. 2.

An enlarged view of the back of the patient, showing a more advanced stage than in Fig. 1.

allowed to get up, but she was cautioned to carefully avoid exposure. On the 19th the eruption had entirely disappeared, the skin had become clear, was free from any staining, and looked healthy; but from fear of too early exposure the patient was retained in hospital until April 9th, when she was discharged apparently well though not feeling very strong. On May 24th the patient was still free from any kind of eruption, but she was weak and debilitated, and though able to get about and look after her family, expressed herself as not being strong enough for half a day's good work; this, however, may in part be accounted for by the fact that that she was unable to get a very strengthening diet.

Medical Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Adjourned Discussion on Difficulties in the Use of the Curette.

A MEETING of this society was held on July 11th, Dr. CLEMENT GODSON, President, being in the chair.

Dr. PURCELL showed three specimens of Carcinoma of the Uterus, removed by Vaginal Hysterectomy. In two of the cases amputation of the cervix had been performed two months and eight months previously, respectively. All three cases recovered from the operation. The first showed signs of recurrence in the vaginal roof six months later. The other two, done more recently, were so far free from recurrence.—The PRESIDENT, Dr. MACNAUGHTON-JONES, and Dr. BANTOCK held that these cases illustrated the futility of amputation of the cervix for malignant disease as a rule, though they had had cases which remained free from recurrence for eight years (Dr. Bantock's case) and for twelve years (the President's case).

Dr. BANTOCK showed three specimens: (1) Large Pedunculated Myoma of the Uterus, with Twisted Pedicle (the tumour was found by microscopic examination to be fibro-sarcoma); (2) Pyosalpinx, with Fibroid Tumour (in both these cases hysterectomy had to be performed); (3) Par-ovarian and Large Ovarian Cysts on the same side.

Mr. H. BELLAMY GARDNER resumed the adjourned discussion on Dr. Fancourt Barnes's paper on Some Difficulties in the Use of the Curette. He had seen the operation performed fifty-seven times by twelve operators in the theatres of two London hospitals. He submitted the following points: (1) the cervix was best held by two volsella on each lip, to equalise the traction; (2) dilatation was facilitated by immersion of the dilators in very hot water; (3) hollow metallic dilators, wedge-shaped in longitudinal section were the best; (4) the best curette was the sharp-edged, spoon-shaped dashing curette; (5) after curetting the cavity should be swabbed out with iodised phenol, an iodoform pencil placed in the uterus, and the vagina packed with iodoform gauze; (6) the scrapings should be examined microscopically.—Dr. ROUTH, while thinking that tents were too much neglected, was glad to hear the sponge tent condemned. Even laminaria tents were not always safe unless properly prepared, and so he always prepared his own. If the os was small it was better to wait till the menstrual period, when some degree of dilatation occurred; and if the uterus was hard it could be softened by placing glycerine tampons in the vagina. It was not always necessary to dilate fully; the greater the dilatation the greater was the risk of perforation. He advised curetting for disease of the appendages, whereby the need for their removal was often obviated.—Dr. HEYWOOD SMITH remarked that the finger-nail was not much use for curetting, except in obstetrical cases, because of the difficulty in bending the finger inside the ordinary uterine cavity. The best curette was Bell's "dredge" curette or Jessett's modification of it; it ensured the complete removal of all the diseased tissues. By using tents first and metallic dilators afterwards, the risk of tearing was diminished. When there was inflammatory disease of the appendages it was safer to defer curetting till the inflammation had subsided.—Dr. MACNAUGHTON JONES said that he had heard nothing new on the subject of curettage in this debate, which had diverged rather into one on dilatation of the uterus than on curettage. Some views advanced on the last evening were certainly startling to any modern gynæcologist. Fifteen years' use of the curette had not, in a single instance, given him an untoward result. The adoption of strict antiseptic precautions before, during, and after operation; securing and maintaining sufficient dilatation of the cervical canal and suiting the use and action of the curette to the particular case requiring it, were the main points to attend to. Certain inflammatory states of the peritoneum and the adnexa were clear contra indications. The best means of dilating the uterus up to a certain point was the laminaria tent of sufficient length and calibre, assisted finally, if necessary, by uterine dilators, as it might often be needful to explore the uterine cavity with the finger. This we might not be able to do if the uterus were fixed and high up in the pelvis. The particular curette selected should depend as to shape and size upon the special action demanded of it. Much larger ones were occasionally used than those referred to. Chromic acid, in various strengths according to the case, was an admirable application after curettage. He invariably used iodoform gauze to carry into the uterus where there had been suppurative endometritis, tamponing the vagina with the same. Contrary to the practice of some, after the first forty-eight hours he replaced the iodoform roll, cleansing out the uterus before doing so with an antiseptic solution, daily. He believed the mischief arising from tents to be mainly attributable to their being left too long in the uterus. If tents of different sizes were used, dilatation under any circumstances was comparatively an easy and harmless process. If the curette were pushed through a friable uterus, or used where it should not be, a death followed, then the fault was not in curettage. It had given him splendid results in cases of suppurative endometritis, plastic and granular endometritis, and in adenomatous growths from the endometrium. Dr. BANTOCK agreed that it was impossible to curette without previous dilatation. He left the tent in till it came away easily, for he thought it did less harm to leave one in for twenty-four or forty-eight hours than to change it every twelve hours. Sponge tents were safe if properly prepared; their action was gentle, and in cases of fungous endometritis the granulations got caught in the meshes of the sponge, and came away when it was withdrawn.—Dr. FANCOURT BARNES said, in reply, that when he heard of curetting being done without dilatation he could only assume that the curetting had not been done at all. He had hoped to hear something said about drainage; he thought that for this purpose an iodoform pencil answered better than iodoform gauze. He was glad that his condemnation of sponge tents was in the main endorsed by the Fellows.

Reviews and Notices of Books.

Medical Partnerships, Transfers, and Assistantships. By WILLIAM BARNARD, M.A., LL.B., Barrister-at-Law, and G. BERTRAM STOCKER, Managing Director of the Scholastic, Clerical, and Medical Association, Limited. London: Stevens and Sons, Limited. 1895.

EVERY Englishman is legally presumed to be instructed in the laws of his country, and therefore there can be no harm in a medical practitioner, whether about to purchase a practice or a partnership or to engage an assistant or be engaged as such, becoming to a certain extent acquainted with the statutes and decisions applying to his transactions and the disputes resultant therefrom. Every medical practitioner also has, before duly qualifying as such, been brought into contact with a certain number of those who have been able to inform him of the difficulties which may surround his future career. Still, he may like to see the advice he has been offered imparted with the authority which print commands, and marshalled in an orderly manner. Hence the perusal of the volume produced by Messrs. Barnard and Stocker by anyone about to enter upon any of the enterprises suggested in the title will repay the trouble taken, as long as the reader bears in mind that no book can do more than occasionally prompt or supplement the recommendations of good sense or experience in practical matters; while in matters legal, directly any complication or difficulty has arisen, the best legal advice should promptly be sought and acted upon.

Mr. Stocker, as the managing director of the Scholastic, Clerical, and Medical Association, has acquired experience of the points which have to be considered from a practical point of view by those for whom he is in the habit of acting. From a practical point of view accordingly he contributes the first part of the book, setting-out draft forms of (1) articles of partnership; (2) a deed for the assignment of a practice; and (3) an agreement between a medical man and his assistant, with comments thereon, prefacing his contribution with a chapter on the valuing of practices, and concluding it with a few words on the system of entering an agreement for an assistantship with a view to becoming a partner. Such

Digitized by Google

agreements as those last referred to Mr. Stocker unhesitatingly condemns, apparently on the ground that they frequently do not result in partnerships; but whether those who have been enabled by them to avoid an association which would have been distasteful or objectionable would view the matter in the same light is doubtful. But throughout the book Mr. Stocker is particularly careful of the wants of the beginner, probably holding that it is those whose experience is necessarily *nil* who are most likely to turn appreciatively to him for guidance. To them he is careful to supply every possible hint, giving an exhaustive list of matters for which money must be reserved in addition to the premium paid for the practice, as well as much sound advice.

Of the second half of the book we are almost inclined to say that there is not quite enough law in it for a lawyer and rather too much for anyone else. The Partnership Act of 1890 is set out, with notes on sections likely to affect medical men, and chapters follow on Goodwill and Restrictions on Practice, with an appendix of Cases on Restrictive Covenants; on Introduction to Patients; and on Assistants. No doubt of the cases which come before the courts a great number are those in which points of law as to the legality of a restrictive covenant arise, but it is open to doubt whether a medical man, having realised that such restrictions must be "reasonable in reference to the interests of the parties concerned and reasonable in reference to the interests of the public," either need or could be expected to wade through the numerous cases cited in an abridged form or otherwise referred to, while a lawyer either settling a covenant or certainly when advising on a dispute concerning one would require the authorities themselves. A fuller knowledge of the law relating to a particular subject and the principles governing it is sometimes gained by reading an exhaustive judgment, which criticises and compares all previous decisions, than by studying brief accounts of them isolated from one another. For instance, the elaborate judgment of Mr. Justice Hawkins in Robb *v.* Green, now confirmed on appeal, though presumably too recently delivered to be included, would have contained pretty nearly all that could be said as to a servant who makes wrongful use of information derived from the fiduciary position in which he finds himself. But, again, such a case is only in a measure practically applicable to medical matters, and in that and many others it is not easy for anyone not a lawyer to advise himself. In practical matters it is best for the medical man to use every means possible by judicious enquiry and otherwise to insure that his partnership or practice may if possible be purchased from a man of honour and integrity, and that no mistake on his own part may jeopardise his future peace of mind; while if he gets into a dispute and legal process seems inevitable, the sooner he refers the matter to a capable lawyer the better it will be for him. To deal with it by himself with the aid of the best text-book in the world will be only a shade less risky than for a lawyer to perform on himself a comparatively easy operation after borrowing a set of instruments and a manual of operative surgery.

With regard, however, particularly to Mr. Stocker's share of the book and the draft agreements which he gives, one thing must be borne in mind. It is of no use to go to a solicitor, who perhaps has never before drafted a deed disposing of a medical practice or a share of it, and to expect him to foresee all the contingencies which may arise and to guard against them. Nor, as has been suggested, can a medical practitioner always recall all that experience should teach him; hence it is not difficult to predict that Mr. Stocker's forms may often prove extremely useful as a foundation to work upon; while the whole of the book should be of service to country practitioners in the legal profession who have not large libraries to consult.

Allgemeine Physiologie: ein Grundriss der Lehre von Leben. Von MAX VERWORN, Dr. Med. et Phil., *Privat-docent* der Physiologie an der Medicinischen Facultät der Universität Jena. Mit 270 Abbildungen. Jena: Verlag von Gustav Fischer. 1895. (General Physiology: an Outline of the Science of Life. By MAX VERWORN, M.D., Ph.D., Tutor in Physiology at the Medical Faculty of the University of Jena. With 270 illustrations. Jena: Gustav Fischer. 1895.)

THIS is a work which we venture to think will attract widespread attention. Its author has already made some contributions to the study of vital phenomena amongst the lowest forms of organisms, but in the present volume he has done what has, we believe, not hitherto been attempted, that is, to analyse the aims and methods of physiology, and to contribute to the solution of the great problem that underlies it—the nature and meaning of life. It is a task for which few are fitted, for it demands a knowledge of natural science as well as a grasp of philosophic doctrine rarely to be found in unison. To ourselves the book has come as a revelation, not only from the depth of reasoning and the command of facts garnered from all sides that it exhibits, but for the lucidity with which the subject is marshalled and the wide knowledge that is herein displayed. That we are justified in this appreciation will become evident as we unfold the plan of the work. Its dedication to the memory of Johannes Müller, the founder of modern physiology, implies something more than a tribute to the life-work of that illustrious man. The author desires to recall the lines of modern physiological research to the sphere which Müller opened up, but which has been somewhat neglected in the highly specialised search after new facts in the intricate mazes of "advanced" physiology. Müller rightly appreciated the truth that physiology—the science of life and of living things—must embrace in its purview research into the conditions of existence in all organisms, that comparative physiology had as much to teach as human physiology as regards life itself. The complex manifestations of the activities of the living body, as witnessed in the highest scale of animal life, can be reduced to a few simple properties of living matter in the lowest organisms, and the secret of life which is concealed in the complex inter-actions of muscle and nerve may be found more readily in the properties of elementary protoplasm.

What is life? The answer to that question, which necessarily stands at the root of all physiological research, has not been invariably the same. Primitive man—nay, even the cultured Greeks and Romans—conceived the wind and storm, the rivers and seas, to be living, or the expression of the will of living beings—doubtless influenced in the thought by the association of movement with vital manifestations. But we know that motion is not essential to life; that death may be simulated by cessation of activities and yet life still be present; the dried seed contains within it potential life, which springs into activity when subjected to favourable conditions; and if the view be extended to microscopic objects, it is asked, how can one distinguish between the spores of torula and the oil-globules in milk—passive as they both are—whereas the minute lime crystals from the abdominal sacs of the frog, viewed under the microscope, are seen in constant movement? It is the first duty of physiology to determine the dividing line between the living and the lifeless in nature. The aim of research is the discovery of the causes of phenomena—to satisfy what Dr. Verworn terms the "craving for causality" (causalitäts-bedurfniss)—a craving which is never satisfied! In the inorganic world we speak of "matter" and of the "atoms" into which it is decomposed, without, however, being able to prove, but only to infer their existence. In the like endeavour to explain vital phenomena we are met with the apparent contradiction of psychical manifestations side by side with corporal, and even when they can be brought into the same

Digitized by Google

causal relationship—and referred to the motion of matter—the problem of life is no nearer a solution. The author in an interesting review shows how physiological ideas and inquiries have progressed from antiquity through the age of Galen, of Harvey, of Haller, and Johannes Müller. In a few passages he sums up the gains to knowledge already obtained by the labours of physiologists, and shows how in every department of the functions of the body crucial questions have received no answer. Then—speaking of the relations of psychology to physiology—the question of the limits placed to natural knowledge is discussed, how we cannot explain "consciousness" in terms of matter; how, indeed, the riddle of matter and force is well-nigh insoluble, so that, as Du Bois Reymond said, the motto of natural science in this regard should not be "ignoramus," but rather, for all time, "ignorabimus." Passing this matter the author touches on the relationship between the material world and the Psyche, and it is interesting to find him practically adopting the Berkleyan philosophy, in the statement that the outer world exists only in our consciousness, nay, even that one's own individuality—the ego—forms but part of the general conception of external things. In other words, the author declares himself a "monist"—i.e., psychical rather than materialistic. From metaphysics he passes to consider the doctrine of "vitalism," and thence to the demonstration that in cellular physiology alone can we hope to solve the riddle of life. He says (page 56): "In physiology we must continually revert to the standpoint which made the researches of our great master, Johannes Müller, so fruitful. During his whole life Johannes Müller advocated practically and theoretically the view that there is no *one* physiological method, but that every method is right which leads to the goal. He chose his method according to the problem before him, never adapting the problem to the method. It is not the method which is uniform is physiology, but the problem. For the solution of this problem physiology must employ in equal share chemical and physical, anatomical and developmental, zoological and botanical, mathematical and philosophical methods of research, according as it fulfils the special aim. But all should lead to one goal—to the investigation of life."

The words just cited form the closing sentences of the first chapter of the work. In the succeeding five chapters there are treated in turn: the Living Substance, Elementary Phenomena of Life, General Conditions of Life, Stimuli and their Action, and the Mechanism of Life. These topics form the bulk of the book, and are treated in a manner at once systematic and philosophical. Living matter as now existing on the earth is only to be met with in the form of *cells*, either isolated or connected to form a compound organism. The substance of the cell is a viscous mass—protoplasm—investing a nucleus. Chemically, the materials of which living matter is composed form but a small number of the elements found in the inorganic world, but variously combined, some of these compounds—e.g., albumins—being limited to organic beings and not existing as such in non-living substances; and other compounds, as carbohydrates, fats, and simpler materials, which are derived from the breaking up of albumins or aid in their formation; and lastly, salts and water, common to the inorganic world, the last named being essential to the fluidity of living matter and inseparably bound up with it. One by one Dr. Verworn discusses the criteria which have been raised to distinguish between living organisms and non-living matter, dismissing them all as inadequate, until he comes to the final characteristic of the formation of albumin and of its metabolism, peculiar and special to living things, and therefore the essential basis of physiological study.

The elementary phenomena of life are discussed under the heads of Metabolism (Stoffurdesel), Morphology (Formurdesel), Dynamics (Kraft-urdesel), and constitute Chapter III. Here, as elsewhere, abundant illustrations are drawn from the animal and vegetable world, especially from the lowest forms of life, showing how the same factors are at work through all the vital processes. Metabolism consists in the processes which underlie what we term nutrition, the increasing formation and destruction of albuminous compounds. Morphology embraces a wide purview. It is concerned with those structural alterations which are seen on the large scale in the building up of specific characters, the acquirement and transmission of some and the gradual loss of others, according to the law of natural selection. It involves also those form-changes which are seen in the individual and the process of growth and reproduction. It is shown how the truth of Harvey's dictum, "Omne vivum ex ovo," is retained in the truer conception of "Omnis cellula e cellulâ," modern research showing that the union of germ-cell and sperm-cell there is a complete fusion of "protoplasm with protoplasm," of "nucleus with nucleus," of "centrosom with centrosom" prior to the segmentation that issues in the cellular basis of the future being. As regards what we have termed "dynamics," literally changes of "energy," it is shown that the production of motion, of light, of heat, and of electricity can be referred to chemical changes, and that in point of fact these, as all other of the "vital" phenomena, are owing to the continued metabolism of living matter. The next chapter, on the General Conditions of Life, opens up some highly interesting speculations. After showing the dependence of life upon its environment the question is raised whether under other conditions than those known to us life could exist, and this raises the problems of the origin of life on the earth and of its future destiny. There are many who, whilst denying the possibility of spontaneous generation in the present order of things, are fain to confess that there is no other satisfactory explanation for the origin of life on the globe than this—that when the molten mass had sufficiently cooled, and water—an essential of life—with other conditions suitable to the existence of living matter, appeared on the earth's crust, there was developed out of the inorganic materials the primal substance in which life was manifested. Haeckel, the protagonist of evolution, is fain to admit this; indeed, he sees no other way out of the dilemma. According to him the structureless primitive monera-mass of albuminous substance must have been formed in the primal seas, the birthplace of organic life. This hypothesis is, however, only one of many to explain the riddle of existence. Opposed to it is the theory of "cosmozoa," which was favoured by Helmholtz and W. Thomson, and assumes that in some way—possibly through meteorites—the earth received some of the living substance which gave rise to its varied and abundant fauna and flora. On this view the beginning of life on the earth would be only one incident in the life pervading the universe. Again, Professor Preyer, who is not satisfied with either of these theories, for he does not see why if spontaneous generation once occurred it should not continue to be manifested, and who sees no solution to the problem of life in the cosmozoic view, argues that living matter *preceded* lifeless, and that the molten globe contained it, although in different form from the protoplasm of to-day. This theory brings us back to primal conceptions, for it endows with life the great earth-mass itself. Lastly is mentioned the conception of Pflüger, who finds in the radical CN the primal basis of living matter. These theories are criticised by the author, who sums up the argument (p. 319) by declaring that Life is a "function" of the earth's development in a mathematical sense; that living matter could not exist so long as the earth was a fiery fluid globe without a firm crust; but that it *must* have arisen inevitably from chemical changes when the conditions became suitable, and that it must change its form and composition as the external

Digitized by Google

conditions alter in the history of the earth. So that the formation of living matter from "earth-matter" was just as necessary a part of the development of the earth as was the formation of water. From these speculations he closes the chapter with a discussion of death, dealing first with necrobiosis and then with the causes of death, and concluding that as in past æons the earth could not sustain life, so in æons to come it will pass into the state of a dead world once more unable to be the habitat of any living thing. Of the remaining chapters—those on Stimuli and on the Mechanism of Life—we have no space to speak. Needless to say that they abound in suggestive statements and apt examples, derived from the study of the lower organisms. To do full justice to these topics would require lengthy treatment; but their perusal, and, indeed, the whole presentation of the subject, cannot fail to arouse interest and thought. It is to be hoped that this work will be translated into English. It is not a text-book, but rather a valuable and scholarly exposition of the teachings of science, not of biology merely, but of cell physiology, which is not only fascinating in itself, but of abiding interest in the light it sheds on ever-present problems.

Diseases of the Kidneys and Urinary Organs. Vol. I. By Dr. FÜRBINGER. Translated by W. H. GILBERT, M.D., with commendatory letter from Sir Thomas Grainger Stewart, M.D. London: H. K. Lewis. 1895.

THIS is a valuable work on the diseases of the kidneys, and evidently represents a very large amount of practical and literary research considering the enormous number of authorities which are quoted. The book is divided into two parts. The first part deals with the more general symptoms of renal disease, and includes chapters on the presence of albumen, blood or hæmoglobin, and casts in the urine, and also on dropsy and uræmia; the second part deals with the circulatory, inflammatory, and degeneratory forms of renal disease in their more particular aspects. In dealing with "physiological albuminuria" and discussing the clinical value of minute traces of albumen, discovered only by very delicate tests, the practical side of the book is well brought out by the following sentence: "Practitioners should adopt as much as possible the old and reliable procedures of testing for albumen, should not trouble themselves about small unimportant haze but should only reckon with decided deposits, which even at first sight show their importance." In the second part the inflammatory processes are all classed under the head of "Diffuse Nephritis," it being understood that the term does not mean an equal distribution of the process all through the kidney, which probably never occurs. This class is then subdivided into (1) acute diffused nephritis (corresponding to acute desquamative nephritis of Johnson and including the catarrhal or croupous forms of many German authors), (2) chronic diffused nephritis (corresponding to Wilks's large white kidney and Johnson's non-desquamative form), and (3) contracted kidney including all kinds of diffuse nephritis which have the following characteristics—(*a*) contraction of renal elements, (*b*) special clinical course, and (*c*) slow insidious development. The book is very nicely got up and pleasant to read; its views are wide, and if some differ from generally accepted ideas, they make the book the more interesting by the larger field of thought they set before us.

St. John's, Clerkenwell. By JOHN UNDERHILL. With etched plates and other illustrations by WILLIAM MONK, R.P.E. London: Cadbury Jones and Co. 1895.

AMONG the advantages which the world at large has derived from the improvements in the art of pictorial illustration, none is more conspicuous than the preservation of those antique buildings, interesting both in their architecture and associations, which are scattered up and down the old streets and out-of-the-way nooks of London. The photogravure or the burin of the etcher fulfils the condition which the Latin poet desired when he wrote of a monument more lasting than brass, and perpetuates for future generations the semblance of places no longer existing. The enterprise of Messrs. Cadbury Jones and Co. has done this good office for one of the most remarkable of our London antiquities in the very artistic volume, dedicated to the Grand Priory of the Order of the Hospital of St. John, which contains the etchings of Mr. Monk and the descriptive letterpress of Mr. Underhill. The last-named gentleman has told the history of the English branch of the great confraternity of the Hospitallers simply, concisely, and with a generous appreciation of their work both in ancient times and in the present day, while the views of the gatehouse, the church, and the other fragments of the once magnificent Priory now spared to us cannot fail to excite the admiration of lovers of picturesque antiquity, as well as of those who rejoice to see nineteenth century science and beneficence housed in the traditionary abodes of the monastic almoners of the ages of chivalry. Very appropriately have the publishers of this interesting book of remembrance included among their views one which, from its very remoteness in point of date and locality, brings out in conspicuous relief the perennial activity and far-reaching scope of the hospitaller energy. The modern walls of the Ophthalmic Hospice at Jerusalem are a standing witness that, though change and decay may obliterate the external landmarks of chivalric charity, the spirit which once raised these crumbling relics of hoary eld is vital yet; and that men like the late Sir Edmund Lechmere could translate into the formulas of latter-day benevolence the antiquated obligations of the monastic rule and carry the spirit of the crusader, without its intolerance, into the very cradle of the Ancient Order of St. John.

General Surgery and Pathology for Dentists. By EDMUND W. ROUGHTON. With numerous original illustrations. London: J. P. Segg and Co.; Philadelphia, U.S.A.: S. S. White, Dental Manufacturing Co. Pp. 134.

THE value of a manual of this character from an educational point of view is very questionable. Whatever part of medicine is practised as a speciality, be it the eye, the ear, or the teeth, a thorough knowledge of general pathology is requisite and should be obtained from some standard work, while the more minute knowledge of the speciality practised should be gained from books specially dealing with these subjects. We therefore fail to appreciate the title of this book — namely, "General Surgery and Pathology for Dentists." But outside these considerations the matter is insufficient for the wants of the examination in surgery required of candidates for the dental diploma. The author, however, states that it is his hope that the book will save the expense of purchasing a large work on surgery, but we feel that any dental student who trusts solely to the information contained in this book will regret having done so. As examples of this insufficiency of matter we may point out that gangrene receives a page the type of which is well leaded. The discussion of such important subjects as septicæmia and pyæmia occupies scarcely two pages. The style of the author is clear, and the only valuable use to which the volume can be put is for refreshing the memory just previously to examination.

LIBRARY TABLE.

Handbuch der Physiologischer Optik. Von H. v. HELMHOLTZ. 2te Auflage. II. Lieferung. (*Handbook of Physiological Optics.* By H. v. HELMHOLTZ. Second Edition. Part 2.) Hamburg und Leipzig: Leopold Voss.—This part deals first with the determination of distance, in

Digitized by Google

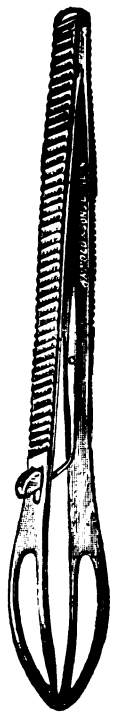
regard to which it is shown that if we attempt to determine distance by the convergence of the visual lines the distance is habitually under-estimated. Then the conditions for seeing vertical lines are considered, those lines being seen vertical to the visual plane that depict themselves upon the meridians of the eye which in the median position of the eye would be actually vertical to the visual plane. In the next place the rules of stereoscopic projection are given and the various forms of the stereoscope are described. Professor Helmholtz has nothing new to tell in regard to the cases of incongruence of the retinæ, and we are still referred back to the old observations of v. Gräfe and of Donders, who are supposed to have proved that many cases of strabismus with single vision occur—a subject that certainly requires further evidence for its support. The difficult topic of the horopter is next discussed, and finally the question of the fusion of double images.

Mercantile Speller: containing the Correct Ways of Spelling Words used in Correspondence. London: R J. Bush. 1895.—This work is much more comprehensive than the older class of spelling books, among which Butter's was perhaps the most familiarly known. No doubt it will be useful to a large section of the writing community, but its value might have been increased by some indication of the preferable or more usual forms in those cases where a large number of alternatives are provided. For instance, nine different spellings are given for the word signifying an Asiatic sabre, all being apparently of equal correctness and varying from "cymetar" to "simitar." "Hallelujah" and "mistletoe" afford similar instances. It is true that these particular words will seldom be required in even the most extensive mercantile correspondence; but the reader encounters some of far less frequent occurrence and of uncertain signification. A few such taken at random are vambrace, vanfoss, vessicnon or vessignon, virose, vug or vugg or vugh or vogle, vughy, wangee or wanghee or whangee or whanghee, whapper or whopper, &c.

Nuova Antologia: Rivista di Scienze, Lettere, ed Arti. Anno xxx., vol. lvii., fascicolo xii. (*New Anthology: Review of Science, Literature, and Art.* Thirtieth Year, vol. lvii., No. xii.) (June 15th, 1895.) Rome. 1895.—This, the last instalment of a periodical which is to the Italian what the *Revue de Deux Mondes* is to the French reading world, maintains the character it has long established for science at once sound and versatile, and for literature at once masculine and elegant. Certainly the student in quest of a model of the most refined contemporary Italian style could not do better than familiarise himself with its successive *fascicoli*. For the medical public it has the honourable distinction, shared in rather less degree by its French counterpart, of giving prominence to biological, hygienic, and even clinical subjects. To its pages we owe many fine monographs on epoch-making physicians, surgeons, anatomists, and physiologists, conspicuous among such contributions being the *éloge* on Karl Ludwig by Professor Mosso, lately noticed in THE LANCET.[1] To those of the profession whose mental equipment includes a working knowledge of Italian we can confidently recommend the present instalment, not only for Professor Mosso's beautiful and touching tribute to his master, but for the other articles on themes of perennial interest in education, literature proper, and theology. The history of "University Reform in France from the Revolution to the Present Day," by Signor Carlo F. Ferraris, Professor of Statistics in the School of Padua, is well worthy of careful perusal.

Laboratory Guide for the Bacteriologist. By LANGDON FROTHINGHAM, M D.V. Assistant in Bacteriology and Veterinary Science, Sheffield Scientific School, Yale University. Philadelphia: W. B. Saunders. 1895.—This small work can scarcely be spoken of as a laboratory guide. It is rather a series of notes, somewhat disconnected in character, made in the laboratory. The author states that the technical methods are specially intended for convenience in laboratory work and that they are now given to enable the laboratory worker to avoid long search through various text-books in which these methods are published. We are afraid, however, that except for the most elementary students these methods are already described in most of the earlier text-books which are now at the disposal of most laboratory workers. The methods that are given are good ones, and some of the practical details may be of use to laboratory workers; but the book, taken altogether as a guide to laboratory work, is far from being complete. On the one hand, it could not take the place of the teacher, whilst on the other it would scarcely supplement his teaching in more than a few details. For these few details, however, we may recommend the little work to those who are already able to utilise them.

Index to the First Fifty Volumes of "The Practitioner, a Journal of Therapeutics and Public Health." London: Macmillan and Co. 1894.—Fifty volumes of the *Practitioner* form a great storehouse of information relating to most departments of medical knowledge, and this copious index is a means of referring to their varied contents, which a large circle of readers will cordially welcome. In turning over the pages the reader cannot help observing how the progressive character of medical science is evidenced by the frequent occurrence of words and expressions which were in very slight request when the journal was established in 1868. The first mention of chloral, for instance, is in vol. iv., of bacteria in vol. ix., of salicylic acid in vol. xiv., of cholecystotomy in vol. xxi., of acromegaly in vol. xlii., of nephro-lithotomy in vol. xlvi., and of thyroid extract as a remedy for myxœdema in vol. xlix. A somewhat puzzling feature is the indexing of the same author under separate but successive headings, sometimes without obvious motive and sometimes apparently only because he has in course of time acquired additional qualifications and titles—for instance, the late Dr. Murchison is entered once as "Murchison (Dr. C.)," and again as "Murchison (Dr., LL.D., F.R.S.)." Similar instances may be found under Gairdner (W. T.), Murphy (Shirley F.), Napier (A. D. L.), Nettleship (Edward), Noel Paton (D.), Pick (Professor), &c. A useful addition would have been mutual cross-references to synonyms lying some distance apart, such as Carbolic Acid and Phenol, Lead-poisoning and Saturnine Poisoning, Phimosis and Phymosis, &c.



Vital Statistics of Boston and Philadelphia, covering a period of six years ending May 31st, 1890. By JOHN S. BILLINGS, M.D., Deputy-Surgeon-General, U.S. Army. Washington, D.C.: Government Printing Office. 1895.—This volume of 269 large pages is one of the publications of the United States Census Office, and presents with great fulness and minuteness of detail the vital statistics of the two cities named, containing respectively populations of 448,477 and 1,046,964. A prefatory letter, addressed to the Secretary of the Interior, states that "this report presents a number of features which are new in the line of census work, such as the sub-division of the cities into sanitary districts and the analyzation of the effect of immediate surroundings of stated conditions upon the death rates of different races and classes of people." Twelve coloured double-page maps, six for each of the cities, are a special feature of the work, which deserves, and will no doubt receive, the close attention of sanitarians and statisticians.

New Inventions.

IMPROVED ARTERY FORCEPS.

ONE defect of nearly every pair of artery forceps is the smoothness of the handles for quite half their length. In the operation of tying an artery it is expedient that the assistant's finger and thumb holding the forceps should be as far from the wound as possible, so as not to be in the way and in the light; but it is not particularly easy to hold on to the smooth end of the forceps, and if the grasp be on the roughened portion further down there is a considerable chance of loosing the catch. Also artery forceps make admirable tenacula for small tumours and the like; here, again, the further the pull the easier the work. So I have had the accompanying artery forceps made to my design by Messrs. Arnold and Son, having the sides roughened for about three-quarters of their length, and so affording an excellent hold.

E. MANSEL SYMPSON, M.D.,
Surgeon, Lincoln County Hospital.

A SELF-LIGHTING GAS-BURNER.

ALTHOUGH the principle upon which the working of this attractive device depends has long been known, yet it has not until now been successfully applied in practice to the automatic lighting of gas. So far back as 1823 Döbereiner observed that when a current of hydrogen impinged upon that peculiar variety of platinum known as platinum black, or spongy platinum, heat was developed until the intensity of it was such as to cause the platinum to glow and eventually to ignite the hydrogen. Döbereiner constructed a lamp which consisted essentially of a hydrogen generator (zinc and sulphuric acid being employed for this purpose), provided with a jet from which the generated hydrogen issued upon a small cage containing spongy platinum. The explanation of this peculiar phenomenon is simply that platinum has the power of absorbing or "occluding" hydrogen and other combustible gases as well as the oxygen of the air within its pores, and bringing them into such intimate contact that union results. In short, combustion ensues and the platinum glows. Perfectly clean and chemically pure platinum effects the same thing, but it does not appear so active and reliable as the spongy variety. Even the latter fails from some cause or other now and again. To Mr. Duke, however, of 20, High Holborn, W.C., belongs the credit, so far as we have experimented, of overcoming this uncertainty. How this has been achieved we do not know precisely, but we are told that the self-lighting burner bearing his name was the result of several years' study, and, we may add, his labours have been rewarded with apparent success judging from the satisfactory results we have obtained with the new self-lighting burner recently examined. Its construction is simple enough. An ordinary batswing burner, provided with a governor, has soldered on the side of it a small brass rod, on the top of which is a cap of black spongy material, presumably platinum. From the apex of this cap projects a thin platinum wire in the direction and on a plane with the base of the flame. On turning on the gas a current, which forms the blue part of the flame when ignited, impinges directly on the metallic spongy mass, with the result that it soon begins to glow, heating the platinum wire to a bright red heat, which then ignites the escaping gas, the whole action being completed in the tests we have made in less than eight seconds. The convenience of such a device hardly needs emphasising. It is no small advantage of the electric light that it can be turned on by merely "switching" and without resorting to the use of matches. The little platinum automatic igniting torch which Mr. Duke has perfected would seem now to offer the same advantages in gas lighting. It will prove most useful where light is wanted in emergency, as in the sick room, while it dispenses with keeping a small jet constantly burning, the accidental extinction of which, as by a draught, may involve risks not only of coal-gas poisoning, but also of explosion. If it were possible to apply it this invention would obviously be a most valuable adjunct to gas fires.

HARTMANN'S HYGIENIC TOWELETTES.

THESE towelettes, also known as wood-wool diapers for ladies, have been for many years so favourably received that a detailed description is hardly necessary. The absorbent pad is very light and soft, closely resembling cotton wool, and is enclosed in coarse gauze, the ends of which are long, for the convenience of fastening. This material readily takes up fluids of the consistence usual in discharges, being comparatively free from the disagreeable tendency to become coated with them superficially. Towelettes which have served their purpose are burnt. They are of various qualities and prices, from a shilling per dozen upwards, the most substantial form being intended for use after accouchement. The manufacturers have adapted their wood-wool to several other purposes of a similar nature, such as infants' napkins and sheets for use during accouchement. These last are in three sizes, the largest being thirty-two inches square; in addition to being soft, comfortable, and inexpensive they absorb the discharges completely and are burned after use, thereby reducing the chances of septic infection. The office of the company is at 26, Thavies-inn, Holborn-circus. Another of their appliances for ladies' use is a stocking suspender, which serves also as a support for the towelettes.

A CABINET FOR PLASTERS AND DRESSINGS.

MESSRS. FERRIS AND CO. of Bristol have forwarded to us a wooden cabinet, about 18 in. long by 13 in. in height and 11 in. in breadth, which is divided into thirteen compartments, each of which contains one of their "ever-ready caddies." The caddy is an ingenious device for keeping in order plasters and other surgical dressings which the busy practitioner is constantly using. Each dressing is wound upon a hollow cylinder, which fixes upon a metal axis running through the middle of the caddy, the caddy itself being an oblong tin box, and when required the dressing can be pulled from its reel and the quantity needed cut off. At the end of the caddy is a metal slide, on which is distinctly printed the name of the dressing contained in the box. The caddy is refilled by removing the label slide and taking out the metal axis, which is put through the new roll of dressing, fixed in position in the caddy, and the label slide replaced. The cabinet is a handsome piece of furniture and will be found a useful addition to the fixtures either of the private surgery, or the public dispensary, or out-patient department.

OZANITE SANITARY RINGS.

THESE consist really of large wafers of vegetable parchment containing a definite quantity of pure permanganate of potassium, which, being crystalline, diffuses slowly out when the ring is floated on water. One advantage of such an arrangement is that the purity and strength of the permanganate is ensured. The ring is obviously convenient and useful for a variety of purposes, while it may be used with confidence for the delicate requirements of a gargle or as an application for cuts and wounds since the materials are quite pure and the paper free from injurious colouring substances. Meritorious as in many respects we concede this invention to be, we must enter a vigorous protest against the adoption of the name of a medical man in its title. "The Dr. Latham Ozanite Rings" is extremely objectionable, as our readers will agree.

THE LANCET.

LONDON: SATURDAY, JULY 27, 1895.

THE discussion of the midwives question by the profession continues and does not become less interesting. Two valuable contributions to it were made last week, one by the Edinburgh Obstetrical Society and the other by the Parliamentary Bills Committee of the British Medical Association. The general result of the discussions may be expressed in the two following propositions—firstly, that midwives are needed; and, secondly, that they should act in touch with some medical practitioner. This was the suggestion of Dr. CAMERON of Leeds: "There must be something incorporated in the Medical Acts [rather, we should say, the Midwives Bill] which made it necessary for midwives attending cases being in touch with some qualified practitioner." The whole gist of the demand of the profession should be comprised in these two propositions. At neither of the meetings we refer to did any medical man argue that there was no evil to be remedied, and that the Mrs. GAMPS might be left to a process of slow and gradual extinction. In the Parliamentary Bills Committee of the British Medical Association it transpired that an amended Bill had been prepared by a subcommittee, which is being circulated among the branches. Dr. WOODCOCK of Manchester and Dr. SOMERVILLE of Galashiels spoke in favour of delay and postponement. This is reasonable enough if a definite amended Bill has been presented for consideration; otherwise it is not so. The case, whether simple or complicated, has been before the profession for twenty years. The suffering and the perils of labour go on. Women destitute of the most primary knowledge of the risks of a lying-in chamber or the lying-in condition continue to practise. According to Dr. D. BERRY HART midwives, wholly or almost wholly untrained, attend about half of all the cases. In these circumstances the question should be definitely settled. If the present arrangements are the best possible, by all means let them alone. But if they are not, indefinite delay is unworthy of the medical profession. The Committee alluded to above has so far yielded to the plea for postponing the consideration of the subject, but not before the following resolution, proposed by Dr. BRIDGWATER and seconded by Dr. GALTON, was unanimously passed:—

"That it is desirable that there should be a change in the present system in the practice of midwifery by unregulated, unrestricted, and uneducated women."

The debate in the Edinburgh Obstetrical Society deserves further notice. It was opened by Dr. D. BERRY HART, who remarked on the numbers of ignorant women who attended labours, and advised a compromise in the form of the registration of "midwifery nurses." Dr. BUIST of Dundee favoured the Bill. He would trust midwives if supervised. He had known midwives give opium for albuminuria and ergot during pregnancy. Registration would bring such conduct under notice and discipline. The aim of legislation should be to protect the poor. Dr. CONNELL of Peebles preferred "registered qualified nurses" to registered midwives. He thought it a matter of public health that the State should insure women against labour, doubtless meaning the risks of labour. One speaker said that the life of a country practitioner would be intolerable if there were no midwives. This remark was similar to one made by Mr. JONES MORRIS of Portmadoc at the other discussion, that it could be easily imagined how very convenient it would be for him in a hilly district to know of a woman in remote parts competent to attend cases of natural labour, and, if she found any difficulty, at once to send for a medical man.

Professor SIMPSON thought the creation of a special group of women a dangerous experiment, but considered that women trained for three months in a maternity hospital might be registered. It is not often that Sir WILLIAM TURNER and Dr. TUKE take part in a discussion of midwifery matters. They did good service on this occasion in saying that in an amended Bill, of which they had only seen a copy at the meeting, the restriction of the practice of midwives to cases of natural labour and the limitation of registration of existing midwives to those presenting certificates from a person of authority in the district—points insisted on by the General Medical Council—were omitted. This reading, however, is contradicted by Section 5 in Clause 12, p. 5. The point must be put beyond all doubt. The promoters of this Bill must know that any measure attempting to give midwives a *carte blanche* in midwifery as if they were medical practitioners would meet with the unanimous condemnation of the profession, and could have no chance of passing through Parliament. The discussion in Edinburgh was interesting with respect to the case of Scotland. Some speakers have said that Scotland had no need of midwives. This was a surprising statement to those who reflect on the scattered and sparse population of many parts of Scotland, and what must be the lot of parturient women there? Yet Dr. MACVIE of Berwickshire stated that midwives were unknown in his district. On the other hand, Mr. THATCHER, whose name is of some authority on midwifery in Scotland, on the strength of twenty years' experience as a teacher of nurses, considered that midwives were absolutely essential in Scotland for populous and large colliery districts. Dr. BARBOUR, by way of practical conclusion to the discussion, made some sensible remarks with regard to certain points which would have to be considered in the event of the Bill being extended to Scotland, a course which he seemed to think probable if legislation were once adopted in England.

We can best conclude our notice of these important discussions by commending them to those who are about to take part in what ought to be the larger discussion of the British Medical Association. The question should be raised out of all party and personal connexions. The profession must either attend all midwifery or consent to have part of it attended by midwives. It has the right to demand in the latter case that midwives shall act subordinately—in touch, as Dr. CAMERON says, with some medical practitioner; in short, that they shall be severely

Digitized by Google

restricted to cases of natural labour and liable to censure when they exceed their duties.

THE opinion of clinicians has for years inclined more and more to the view that it is impossible to explain pneumonia as a simple inflammation of the lungs. The abrupt onset, well-defined course, and definite crisis characteristic of the disease, the fact that the pulmonary lesion and the clinical phenomena do not run *pari passu*, the occasional occurrence of epidemics,—these and many other facts point to the conclusion that the true nosological relations of pneumonia are with the specific fevers rather than with the inflammations. Naturally, the cause of pneumonia has been sought for in a micro-organism. There is a certain analogy between the course of the pyrexia in pneumonia and in the various agues, and the discovery of LAVERAN, that the febrile period in ague is coincident with the life-history of the parasite of malaria, has a suggestive bearing on pneumonia. If it could be shown that a special micro-organism is always present in the pulmonary tissue or in the blood of patients suffering from pneumonia, and if it could be demonstrated that the life-history of this micro-organism is coincident with the pneumonic pyrexia, we should have an adequate and satisfactory explanation of the true pathology of the disease. It cannot be said, however, that we have yet obtained satisfactory evidence on these points. FRIEDLÄNDER first described diplococci present in the sputum of pneumonic patients, and these diplococci were encapsuled. Further inquiry, however, proved that these diplococci were by no means constant in the disease; that their presence was, in fact, the exception rather than the rule. Subsequently FRÄNKEL was able to differentiate another micro-organism—the pneumococcus—which he believes to be generally present. This pneumococcus is usually a diplococcus; the prevailing shape, according to Dr. WASHBOURN, is lanceolate, although the individual cocci may be rounded or oval or rod-shaped. They are variable in size and often form chains of four or five cocci, and even in some cases of as many as forty or fifty cocci. They are sometimes with and sometimes without a capsule. The pneumococcus of FRÄNKEL is stated by Dr. WASHBOURN to be capable of exciting pleurisy, empyema, meningitis, and otitis, as well as pneumonia, and it is sometimes present in the secretions from the mouth, nose, and bronchi of healthy individuals. As he points out, this last fact is no argument against the pathogenic *rôle* of the pneumococcus, as the same applies to the diphtheria bacillus, which has frequently been found in the throats of healthy individuals without producing any injurious effects. Mice and rabbits are the most susceptible animals to inoculation of the pneumococcus, guinea-pigs are much less susceptible, whilst pigeons and fowls appear to be immune. The course of the temperature following inoculations in the rabbit would appear to bear considerable resemblance to that of pneumonia in the human subject as regards the nature of the rise and the height attained, but the course of the case is very much more rapid. Thus death or recovery generally takes place within two days. The blood is found to be crowded with cocci within a few hours of the performance of the inoculations.

The true explanation and consequent value of these investigations is eminently a question for experts in bacteriology, and it must be admitted that at present bacteriologists are much divided on the subject. Pneumonia was long the battle-ground of therapeutists. At the present day it is almost as much the battle-ground of pathologists. It is not too much to hope, however, that ere long some consensus of opinion will be reached on this much controverted and very important point. Bacteriologists may be fairly asked to furnish us with definite knowledge as to whether a characteristic micro-organism is uniformly present in pneumonia, and, if so, whether its life history affords any clue to the phenomena of the disease. While this question remains in abeyance the treatment of pneumonia—always one of the most disputable and difficult in the whole range of medicine—becomes more difficult than ever. If the disease be truly parasitic, and if the destruction of the parasite be the true object of therapeutics, then it is evident that the antiphlogistic treatment of former days and the stimulating treatment of the present day are both alike mistaken and futile. Quinine was known to control ague long before the explanation of this fact—viz., that quinine is a germicide to the amœba of malaria—had been attained; but how much more satisfactory is the treatment of malarious affections now that the logical basis of the accepted treatment has been made clear.

As regards pneumonia we have no specific remedy, but it may be fairly enough argued that the bacillary theory of the disease, however problematical it may still remain, suggests the wisdom of caution in pushing either an antiphlogistic or a stimulant line of medication. The reasonable and moderate treatment of symptoms must commend itself to every judicious practitioner; but wholesale bleeding on the one hand, or drenching pneumonic patients with alcohol on the other, seems, in the light of recent researches, more indefensible than ever. Similarly the routine use of antipyretics seems bad practice. All the evidence at our command appears to show that, apart from hyperpyrexia, the height of the temperature bears no direct relation to the danger of the attack in pneumonia. At this point again the uncertainty overhanging the pathology of pneumonia is very embarrassing. Is the pyrexia the reaction of the organism to the action of a morbid substance—whether bacillary or not—in the blood? Is it simply the effect of such a poison, or is it the effort of the organism to rid itself of the poison? In other words, as Dr. HALE WHITE puts it, is the pyrexia one of the "defensive mechanisms" of the body? We cannot answer these questions with any confidence or certainty in the present state of our knowledge, and yet until they are answered our treatment must remain halting and tentative. We trust bacteriology will come to our relief and accomplish in relation to pneumonia something comparable to its great achievements in other fields of enquiry.

THE employment of women, more especially of married women, is a question of admitted importance from a public health, as well as from an economic, point of view, and Miss COLLET'S recently issued report to the Board of Trade on this subject possesses more than a passing interest. The

Digitized by Google

census returns for 1881 and 1891 do not, as she points out, confirm the general impression that the employment of women is rapidly extending—in fact, the proportion of women returned as occupied remained practically stationary during the decade 1881–91, while the employment of girls and women under twenty-five years of age showed an increase during the ten years. Miss COLLET'S report affords conclusive evidence that the employment of married women, and generally of women over the age of twenty-five years, had declined during that period. The increased employment of girls and young women, moreover, occurred, it appears, concurrently with a similar increase in the employment of boys and young men. It is true that a combination of causes, including a diminished probability of marriage, have recently tended to encourage middle-class girls to seek definite occupation in increasing proportion; but Miss COLLET points out that the "industrial position of women, speaking generally, varies with the degree of material prosperity of the men in the class to which they belong," and that the increase of wages and of the general standard of comfort among what are called the "working classes" have in recent years enabled the services of the daughters to be retained at home in increased proportions. In the general English population, of 100 girls and women over ten years of age 34·1 were returned as occupied at the census in 1881, while at the more recent census in 1891 the proportion occupied had only fractionally increased to 34·4 per cent. It is an eminently satisfactory fact that above the age of twenty-five years there has been a distinct decline in the employment of women in all factory and workshop trades (except tailoring), as well as in occupations giving merely casual employment. This necessarily implies a decrease in the employment of married women, and it is beyond doubt that the slight increase in the employment of girls and women generally is due to the increase under the age of twenty-five years and to the increased employment of middle-class women mainly in teaching and clerical occupations.

The unquestionable importance of the effect of the employment of married women upon infant mortality, more especially of employment in factory and workshop trades, gives special interest to Miss COLLET'S statistics on this branch of the subject. The census tables do not, unfortunately, afford any direct information concerning condition as to marriage of the women returned as following definite occupations. Indirectly, however, Miss COLLET has been able to show from these returns the minimum percentage of married and widowed women returned as occupied in different sections of the population. For instance, if the number of occupied women exceeds the number of single women in a given population, she correctly assumes that this excess represents the minimum percentage of employed women who are either married or widowed. In one of the tables in her report she gives this minimum percentage of employed married women in 19 industrial English towns, both in 1881 and in 1891, the figures showing a reduction in 1891 of the minimum percentage of married women aged between twenty-five and forty-five years engaged in industry in each of these towns, with the exception of Burnley. These figures undoubtedly justify the inference that, at any rate in these 19 industrial towns, the percentage of married women employed in industry is diminishing. Notwithstanding, however, this tendency towards the diminution of industrial labour among married women, the minimum percentage is still exceedingly high in many of the "textile" towns. For instance, this minimum percentage in 1891 was equal to 18·7 in Preston, 22·1 in Burnley, and 26·6 in Blackburn. Miss COLLET remarks, with reference to these figures, that "in such towns, where nearly all the girls under twenty, and half the women between twenty and forty-five, are engaged away from home, we may naturally look for a high rate of infant mortality, and expectation is justified by the facts." It is undoubtedly true that the rate of infant mortality is excessively high in each of these three Lancashire manufacturing towns, more especially in Preston; but it should be noted that the rate was very considerably lower both in Burnley and in Blackburn than in Preston, although the proportion of employed married women both in Burnley and in Blackburn was considerably higher than in Preston. It is evident that the factory employment of married women, deleterious as it must be to infant life, is not the controlling factor of infant mortality. In proof of this it may be noted from Miss COLLET'S table that the proportion of employed married women is nearly twice as high in Bradford as it is in Leeds and Huddersfield; the rate of infant mortality last year was, however, considerably lower in Bradford than it was either in Huddersfield or in Leeds. It is, moreover, a fact that infant mortality is persistently high in the mining districts of Durham, Northumberland, and South Wales, in which the industrial employment of women is considerably below the average.

From special returns furnished to the Board of Trade and utilised by Miss COLLET in her report, it appears that 32·9 per cent. of the women aged upwards of eighteen years employed in the cotton mills of Lancashire and Cheshire were either married or widowed; in the woollen mills in Yorkshire 29·8 per cent.; and in the worsted mills in Yorkshire only 21·2 per cent. Miss COLLET, after careful examination of these returns, comes to the conclusion that there is no ground for doubting their approximate accuracy, except that there may be a tendency to return unmarried women with children as married. It is evident, therefore, that the proportion of employed married women is far greater in Lancashire than in Yorkshire, and this may partly account for the greater excess of infant mortality in Lancashire, although the lower general sanitary conditions of the Lancashire towns cannot be ignored as an important factor of the excessive infant mortality therein. It is much to be hoped that Miss COLLET will be able to further investigate this important question of the factory employment of married women, with special reference to its influence upon infant mortality. A more exhaustive and elaborate analysis of the census returns in the various industrial towns, to which she has had access, with a view to determine the ages of the married women employed, and the numbers and ages of their children at the time of the census, would throw much additional light upon the extent to which young children in these towns are deprived of their mothers' care and attention, and would supply a more accurate basis for calculating the true effect of the employment

Digitized by Google

of mothers on infant mortality. We cannot, however, speak too highly of the value of Miss COLLET'S report and of her conclusions that there has been recently no general increase in the industrial employment of women, and that as regards such employment of married women there has been an undoubted decline.

Annotations.

"Ne quid nimis."

THE GENERAL ELECTION.

THERE can no longer be any doubt as to the result of the General Election. The Unionists will be returned with a very large majority and untrammelled by any special pledges. About the general line of their policy there cannot, however, be much room for doubt. Its tendency will be the opposite of that pursued by the Government which it supplants. We have, as medical journalists, nothing to do with politics, except in so far as they are likely to affect questions of public health, the progress of national hygiene, and the interests of the medical profession. We are always ready to welcome and press forward to the best of our ability any earnest and good work and any legislative attempts in these directions from whatever source they may come. Like all stories worth the telling, the moral of this election lies upon the surface, notwithstanding that it will be differently read in the light of party bias and interest. The next parliament will see a strong Government, not harassed and embarrassed by doubtful votes, but homogeneous in its construction, and not dependent for its existence on adjusting in harmonious action a number of different parties, each intent on pursuing and obtaining its own end. The present Government is relatively unpledged. With such a majority the fear will rather arise from within than without lest it should disintegrate from the size of the Cabinet and the carelessness of Members in the performance of their duties and in their attendance at the House. There will, at any rate, be time, under the circumstances, for a policy of natural evolution, and the Government will have no temptation to keep itself *en évidence* by ambitious, far-reaching, and contentious legislative measures that, rightly or wrongly, in the eyes of many practical, sober-minded people, seem to be a policy of revolution. The interests of the nation, assured of the result of the General Election, is now focussed in the inquiry, "What will they do with it?" Whatever else may be done, there are several important matters of public health calling for attention, and there is plenty of room for the prosecution of work of a hygienic and domestic character affecting the health and well-being and every-day life of the people of the British Empire. Attention to these matters may not have the glamour attending legislative efforts of a larger and more ambitious sort, but it will be largely productive of the comfort and contentment of the people, give scope to successful commerce and labour, and sweeten the breath of society from the peer to the peasant. A late Prime Minister was not far wrong when he emphatically summarised the national importance of sanitation in a phrase, and the new Ministers will, among other things, have to fulfil the expectations they have raised by their expressions of sympathy with the social and sanitary requirements of those who live and labour in our large cities, towns, and villages.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE letters of the Lord Mayor, Sir Joseph Renals, and of Sir Sydney Waterlow appealing to the benevolent of this [illegible]hy metropolis to bring the Fund for this year up to £50,000 deserve a generous response. It is gratifying to learn that Sir Sydney Waterlow estimates already that the yield of this year's collection will be £46,000. The amount available for distribution will evidently exceed that of any previous year. This is one side of the question—the pleasing and the creditable side. But there is the other, neither pleasing nor creditable—1901 beds unoccupied and empty. There is no question here of abuse of hospital charity. It needs no excess of imagination to realise how many sufferers there are in the one-room and two-room families of London who would be immensely benefited by a few weeks in a well-found hospital. Let it never be forgotten that nearly one-sixth of the families of London, according to the last census, are living in one room each. A larger collection would give to them some or all of these 1901 beds. Is it too much to ask for a few large subscriptions towards this most desirable result? The clergy and the ministers have done their part. Many of them represent congregations of most limited means. Out of deep poverty much of this collection has come, and from churches which have enough to do to make ends meet. If the £50,000 on which the council has set its heart, and which is surely not an excessive demand, is to be completed it must be by rich men casting into the treasury. The Fund was never better administered. The unworthy are excluded, and the more meritorious and needy are taken into account. We trust that before the meeting of the council on Monday at 2.30 P.M. the Lord Mayor, whose efforts in this matter have been very praiseworthy, will be able to announce that the sum wished for has been raised, and that the hearts of all who believe in our voluntary hospital system have been rejoiced.

WATER-SUPPLY IN RURAL DISTRICTS.

To procure a proper water-supply for isolated houses and small groups of houses is a problem the satisfactory solution of which often taxes to the utmost the ingenuity of the medical officer of health, and it must be confessed that in some instances it seems as if the difficulty of obtaining a supply altogether above suspicion produces a condition of the executive in which all action is paralysed and the inhabitants are left to obtain their drinking water from shallow wells from which no attempt has been made to exclude surface water, or even from neighbouring ponds or ditches. How much the comfort of all classes of our rural population depends upon the knowledge, activity, and influence of the medical officer of health may be seen by comparing certain rural districts with one another, comparisons which probably many of our readers are quite capable of supplying from their own personal experience. As instances of what may be done by an energetic medical officer of health familiar with the local geology, may be mentioned certain rural sanitary districts in Essex, over the health of which one who has now been appointed the county medical officer of health has for some years past presided, and owing to whose efforts people of all classes living in the districts in question have been furnished with a pure water-supply. Dr. Darra Mair, the medical officer of health to the Croydon rural sanitary district, has, too, done much in a similar direction, and he has recently presented to his sanitary authority a report showing that the work is not yet finished. The district referred to is, we believe, as a whole well supplied with water, it being exceptionally situated in this respect by virtue of the many water mains which traverse or abut upon it. It appears, however, that in portions of the parishes of Coulsdon, Addington, and Woodmansterne there obtains a state of affairs which should certainly be at once remedied. Coulsdon is the parish where matters are worst, and here we learn there are between forty and fifty houses solely dependent on rain water for their supply. These houses possess underground covered

Digitized by Google

tanks in which the water is collected from the cottage roofs, and the supply of which, owing to the recent drought, has been much reduced and in some cases quite exhausted. Even where there is still water, it is, Dr. Mair tells us, "muddy and crowded with visible animal life." Some of the houses possess no tanks and are dependent for their supply upon a pond which, we regret to relate, is vested in the sanitary authority and the water of which "has an abominable stench when disturbed, evidently due to decaying vegetable matter." It is hardly to be wondered at that under these conditions the tenants complain of their water-supply and fear to drink it unboiled, or that its consumption in persons newly arrived in the district tends to produce acute intestinal disturbance. Small wonder, too, that the cottagers convert their water into ginger-beer or lemonade in order to conceal its nauseous properties. How much of the "summer drink" of country tourists is thus concocted?. Dr. Mair, in his report, points out to the Croydon rural district council their powers and responsibilities under the Public Health Act, 1875, and the Public Health (Water) Act, 1878; and, in our opinion, he has adequately established that the existing supply of the houses referred to is both insufficient and unwholesome. Upon the rural district council now rests the responsibility.

NEWSPAPERS AND LIBEL.

A CASE has just been tried in the Supreme Court of West Australia which has great interest for medical men. The plaintiff, Mr. C. B. Elliott, Government medical officer in Geraldton, sued the Victorian Express Newspaper Company for libel. The libel was contained in the form of a letter, which letter implied that the large number of cripples in Geraldton was owing to the incompetence and neglect of the hospital medical officer, Mr. Elliott, and he accordingly asked for £2000 damages. There seems to have been a large amount of personal feeling exhibited by the writer of the letter, and a variety of witnesses were called to prove neglect and malpraxis on the part of the medical officer. After a trial which lasted eight days the jury awarded Mr. Elliott £500 and costs, the editor being also sentenced to fourteen days' imprisonment for some contempt of court occurring during the trial. While we congratulate Mr. Elliott upon his success, we feel bound to remark that the Geraldton Hospital does not seem up to the modern standard in many ways, and also that people should not set one man to do an amount of work which would be enough for ten.

DANGEROUS EXHIBITIONS.

AN incident recently took place at the Royal Aquarium which, though happily unattended with any serious consequences, shows forcibly the dangerous character of certain public exhibitions. A girl performer on the high trapeze missed the trapeze for which she was making, but managed to catch one of the tie-rods of the roof, where she had to remain some time until she let herself go and fell into the net. We have not the details before us, but it is evident that the child—for we believe she was no more—might easily have lost her life except for her pluck and presence of mind. We are fully conscious of the grace and beauty displayed in trapeze exercises, but the point we take exception to is the element of danger which enters into these feats when performed at a height of 90 ft. or 100 ft. above the ground. Just as much skill, just as much grace, just as much practice are needful for the performance of gymnastics on a trapeze ten feet from the ground; but the fact is that the British people, like all peoples, has a morbid liking for looking at spectacles when there is a possibility of "something happening." Hence the popularity of shows like the one of which we are speaking, fancy shooting exhibitions, where a mark is placed on a man's head, &c. It is just as difficult to hit the ace of hearts when nailed up on a board as when it is placed upon a man's head, if we except the possibility of nervousness on the part of the shooter; but the one exhibition will draw a crowded house while the other will be a "frost." We are no advocates for grandmotherly government. If a certain class of idiots like to go on to thin ice we see no reason why they should not, except for the fact of their spoiling the ice; but no trading company should be allowed to make money out of risking other people's lives. The management of the Aquarium is, we know, very careful to minimise risk as much as possible, but even a net is not always a certain safeguard; and when, as we have said, the skill of the performer is equally displayed when the danger is absent we fail to see why the element of risk should be allowed.

COUNTY COURTS AND MIDWIFERY ENGAGEMENTS.

IN another column will be found a report of a case in the Holywell (Flintshire) County Court, in which a physician and surgeon, Mr. J. William Parry, of Bagillt, sued John Venables Price for £2 8*s*. This sum represented 6*s*. balance of an old account and a fee of one guinea each for two engagements to attend Mrs. Price in her confinement. The first engagement was in July, 1893, and the second in April last. In neither case was the plaintiff sent for. He did not take any action to recover the first fee until the defendant again failed to send for him on the second occasion. The practice of so retaining medical men and then not sending for them being very common in this district, the plaintiff determined to bring the case into Court. The judge said the plaintiff had waived his claim for the 1893 engagement, but allowed a fee of 10*s* 6*d*. for the engagement of 1895. The amount is inadequate, as if the judge had accepted a fanciful theory of the defendant that when the medical attendant is engaged beforehand the fee is half a guinea, but when he is called suddenly a whole guinea. We cannot agree with this part of his Honour's ruling, but it is something to have to record his remark in, reference to people engaging an obstetrician and not sending for him, that "a bargain is a bargain."

RENAL DISEASE AND GENERAL PARALYSIS OF THE INSANE.

IN the last number of the *Journal of Mental Science* Dr. Hubert C. Bristowe recalls attention to a subject to which he has recently devoted considerable study. In a former paper he alluded to the high percentage of patients dying of general paralysis of the insane, who showed signs of chronic changes in the kidney. On considering the possible connexion between the clinical condition of general paralysis and the changes found post mortem in the kidneys, the condition of the arteries seemed to furnish a connecting link. At all events, as was pointed out, a diseased condition of the cerebral arteries occurred in those dying of granular kidneys very similar to, if not identical with, what is found in those dying of general paralysis of the insane. In the present paper an attempt is made to supply the deficiencies in the first. Reference is first made to the statistics of Mr. Beadles and Dr. Bond. The former found that in 2610 cases of insanity there were 1128 cases of chronic renal disease, or 43·21 per cent. Dr. Bond out of 154 cases found 74 cases of renal disease, or 48 per cent. Dr. Bristowe's numbers are 532 necropsies, 327 cases of chronic renal disease, or 61·466 per cent. The exclusion of patients over 60, in whom some chronic fibroid change in the kidney might be present without much significance, reduces the percentage to 52·9, a reduction of 8 per cent. Excluding also general paralytics, a further reduction by

Digitized by Google

12 per cent. is effected; and after making certain allowances Dr. Bristowe makes his percentage of chronic renal disease among the insane, excluding general paralytics, 44 per cent. Among general paralytics he finds the percentage of chronic renal disease to be 72·11, a sufficiently striking difference. Dr. Bristowe next takes the statistics of the Dorchester, Bristol, and Gloucester Asylums with reference to renal changes in general paralysis. At Dorchester the total percentage of diseased kidneys in general paralysis was 71·875, at Bristol 54 per cent., and at Gloucester 74·157. To account for the differences several factors have to be taken account of, and not the least important is the personal factor of the observer. Dr. Bristowe now takes his own figures together with Mr. Beadles' and Dr. Bond's, a total of 3446 cases of insanity. Of these patients, 48·867 had renal disease. Reckoning 12 per cent. of these as general paralytics and 4 per cent. as over 60, there is a percentage of renal disease amongst the insane under 60, excluding general paralytics, of 32. Taking, on the other hand, the statistics of the Somerset, Gloucester, Dorchester, and Bristol asylums as regards general paralysis and renal disease, there are 266 cases, and of these 183, or about 68·8 per cent., had renal changes. As Dr. Bristowe remarks, from the statistics it seems justifiable to conclude that in general paralysis renal changes are much more common than in other forms of insanity—that, in fact, they are usually found. Dr. Bristowe briefly considers the question of the cause of these changes, and is of opinion that they depend upon some toxic condition in the blood—possibly alcohol, possibly syphilis, perhaps both; and in concluding his paper asserts that he is still able to maintain, after a wider examination of material, that renal disease of some form is exceedingly common in general paralysis. At the same time, he remarks, it is not clear that the form of renal disease is always interstitial nephritis, and he inclines to the view of Gull and Sutton that there is such a disease as arterio-capillary fibrosis, in which the kidneys are commonly affected. Dr. Bristowe would also suggest that disease of the brain—that disease which manifests itself clinically as general paralysis of the insane—is under some circumstances another result.

THE RED SEA PILGRIM TRAFFIC.

WE learn from the *Times of India* of the 5th inst. that a Government resolution has been passed announcing that a Bill is about to be introduced in the Supreme Legislative Council for the special regulation of this traffic. The changes about to be effected are mainly those resolved upon at the late Paris Convention, and it is proposed to get the Bill passed in time to give effect to the new regulations for next year's *Haj*. Speaking generally, the recommendations of the Paris Convention strike us as very necessary and good. As regards the increased space to be allowed to each pilgrim, the Convention required that twenty-one and a half square feet should be given for each pilgrim of whatever age. The British Government reserved, it will be remembered, the point at the time, but they have now intimated that they will make a minimum standard of sixteen square feet for each pilgrim irrespective of age. There can be no doubt that on sanitary grounds the Convention was right, but unfortunately other considerations come in. Increased space entails increased expense, with the result of raising the fares for the pilgrims and of consequently wholly excluding a large number of poor Mahomedans from making the *Haj*. From the public health standpoint this is a very good thing perhaps, but it must be remembered that the pilgrimage is to Mahomedans a religious act of the most important kind. As regards other matters—the extension of the notice of sailing to pilgrims, the provision that the upper deck shall be clear of all encumbrances and kept exclusively for their use, the increase of hospital accommodation, the medical inspection of all pilgrims previously to embarkation instead of on shipboard, and the new regulations as to water-supply and hygienic arrangements during the voyage—these are matters of common sense and prudence. As regards the embarkation of pauper pilgrims it has been wisely suggested that something should be done with a view to some limitation of the large number of these poor creatures, who yearly make the pilgrimage only to die of fatigue and starvation, by seeing that they are provided with sufficient funds before granting them embarkation tickets. The health officer at Bombay has suggested that the captains of pilgrim ships should be required to keep a return of the number of passengers on the outward and homeward voyages, and that such a supervision over the sale of tickets to passengers should be enforced as to ensure that it is not in excess of the measured accommodation provided on shipboard for each separate class. There are also other details of a minor character which we hope to see incorporated in the forthcoming Bill; but nothing is likely to prove efficacious until some radical changes are carried out at the Cameran lazaretto, and we hope that the British Government will not only put pressure upon the Turkish Government in this direction, but obtain the permission of the Porte to send out some one from this country to see and report upon what is done.

WOODEN-LEGGED PEDESTRIANISM.

NOGENT-SUR-MARNE, a city not hitherto celebrated as a sporting centre, has rendered itself famous by inaugurating a series of running contests for wooden-legged athletes. Not long ago, in response to a general invitation, no fewer than sixty-seven individuals who had lost either a leg or a thigh competed for a number of prizes, the distance to be covered amounting in every case to 200 metres. The enterprising cripples were divided into *cuissards* and *jambards*, and, contrary to what might have been expected, the "grand champion" turned up amongst the former class. M. Roulin, whose thigh had to be amputated in 1887 in consequence of an accident, succeeded in getting over the course (about 220 yards) in the very remarkable time of thirty seconds; whereas M. Florant, the most speedy *jambard*, took thirty-six seconds, and was, moreover, easily defeated by the second and third *cuissards* as well as by the champion. There was also a race for juniors, but the youngsters failed to approach the veterans, the winner's time being thirty-five seconds. The proceedings ended with a *course de consolation*, which was carried off in thirty-three seconds by M. Mansire, but whether this gentleman was a *cuissard* or a *jambard* is not stated. Altogether the meeting, or match as our French friends called it, was a great success, affording endless delight to both competitors and spectators. If a similar show were to be organised in this country it would doubtless be productive of a large sum in gate-money, which might be devoted to some charity connected with athletics, or, better still, be added to the Hospital Sunday Fund. Our contemporary, *Le Progrès Médical*, to whom we are indebted for the foregoing particulars, concludes its article in the following terms: "We have made a point of giving the names of all the *lauréats*, inasmuch as some surgeons may perchance in this way obtain tidings of patients on whom they operated, but whom they have not seen or heard of since, as convalescents, they quitted the hospital." This passage is very satirical (although the writer was probably not aiming in that direction), and might aptly serve as text for a homily on gratitude, or rather on the absence of that sentiment among patients in general. The author of the definition that gratitude is a lively sense of favours to come would of course argue that surgeons have no right to expect any recognition of

Digitized by Google

their services. A man who has lost one leg under the knife does not look forward anxiously to parting with its fellow. Speaking in all seriousness, however, there is probably no class of men whose services to the community are as a matter of course received with less gratitude than those which are rendered by medical practitioners. No other toilers in the industrial hive lead such wearing lives as medical men in general practice, who are compelled to remain on duty perpetually, night and day alike, and yet the meed of recognition they receive is indeed scanty.

THE INDEX MEDICUS.

IN our issue of June 29th we pointed out how important a matter it was that the Index Medicus should not be allowed to perish. The yearly cost of production is about £1,000, and it is proposed to raise this sum by 200 subscriptions of £5 each. The United States, it is estimated, will supply 120, Great Britain 60, and the Continent 20. We think, however, that Great Britain with all her learned societies might well subscribe £400 by herself. If £5 is too heavy a tax for one individual to undertake, there are surely five medical men in every one of our large towns, each of whom would subscribe £1, and so form a group which would receive a copy of the Index for their common use; while institutions and societies should have no hesitation in voting the required amount. Those who are willing to subscribe are requested to communicate with the Librarian, Royal Medical and Chirurgical Society, 20, Hanover-square, London, W.

TREPHINING FOR EPILEPSY.

IN a recent number of the *Archives de Neurologie*, Dr. Hallager of Viborg relates a case which presents several points of interest. The patient was a single woman aged twenty-two, in whose family history pulmonary troubles played a considerable part. From the age of twelve the patient herself had at times suffered from chlorosis with palpitation, but had no serious illness until January, 1893, when she became suddenly ill, and was only able to utter the words "Ja" and "Nein." The day after the commencement of her illness she had the first convulsive attack. At this time the right arm was paretic, and a few days later the right leg also was affected. After some weeks she was able to speak, and the paresis gradually diminished, first in the leg and later in the arm. She remained in bed for five or six weeks, and at the end of this time was still unable to read, although she was able to see and recognise letters. Several convulsive attacks took place in the first week of her illness, and she then went for about two months without any. She then had an attack which commenced with shaking of the right arm, followed by elevation of this limb above the head. The right side of the face was then affected and general pain was experienced throughout the body. Consciousness was lost, the convulsions became general and were succeeded by coma. General headache was experienced on recovery from the comatose condition. Apart from some affection of memory the mental condition was unaffected and no distinct paralysis was present. Under treatment by bromides the convulsive seizures diminished in frequency and intensity, but did not cease. An attack which was witnessed, commenced with localised spasm in the right forearm, followed by a continued movement of flexion at the elbow and elevation of the arm. She then lost consciousness, fell down, and became convulsed generally. Attacks of spasm similar to what occurred at the commencement of this attack were also common, but consciousness was not lost and the convulsion was only local. There was no optic neuritis, and it was thought that the lesion determining the attacks was probably the result of hæmorrhage or embolism, and operation was determined upon as likely to afford at least some relief. Trephining was performed in front of the fissure of Rolando, and when the disc of bone was removed the discoloured dura mater bulged through the opening. The opening in the bone was enlarged until normal dura mater was visible all round the discoloured part; the membrane was incised and a sound passed through the congested pia mater into a cystic cavity as large as a nut. This cyst was incised, and its dark brown contents removed, together with the walls of the cyst. After the operation there was weakness of the limbs on the right side, and the patient occasionally experienced muscular spasm in the forearm. About a month after the operation she had two attacks similar to those which had previously occurred. She was put on bromides and remained free from attacks till the time at which the account of the case was written. She was free from pain also, and apart from some impairment of memory and a difficulty in effecting fine movements with the right hand was quite well. The cyst was probably the result of hæmorrhage, as hæmatoidin crystals were found in the detritus removed at the time of operation. As the writer remarks, it is not quite certain what the future of such a case will be. The irritative cyst has been replaced by a cicatrix, with, no doubt, at first some inflammation around it, but it is to be hoped that this will subside and that there will be no recurrence of the convulsive seizures. We would call attention to the similarity of symptoms and treatment in this case to those in Mr. Anderson's case occurring at St. Thomas's Hospital, a full account of which is given in our "Mirror of Hospital Practice" this week.

THE BOILER EXPLOSION IN YORKSHIRE.

ALTHOUGH it is not always possible to foresee and prevent accidents, risk may be greatly minimised when proper precautions are taken, and it is the duty of all employers to see that the rules and regulations made for this purpose are strictly adhered to. But accidents are constantly happening either from wilful disregard of rules by workmen themselves or from apathy on the part of employers or their subordinates in regard to their enforcement. At Warrenby, near Redcar, in June last, a most destructive boiler explosion occurred (recorded in THE LANCET, June 22nd, 1895), which resulted in the death of several workmen besides causing a terrible amount of distress in the district, the inhabitants of which depended almost entirely on the works at which the accident occurred for employment. The Board of Trade inquiry into this catastrophe has elicited the fact that, although the boilers had been pronounced to be dangerous, the heads of the firm were unaware of it through one of their servants failing to make the necessary report. Rightly, the firm has been held responsible, and ordered to contribute towards the cost of the inquiry; but this will not prevent similar accidents from occurring, and it is to be hoped that something may be done in the way of legislation to prevent as far as possible such a catastrophe in the future. This was perhaps the most destructive explosion of the kind that has ever occurred in the north of England, and in some respects unique; but while both men and employers remain apathetic or callous to their danger the occurrence of such accidents should not excite wonder.

MONUMENT TO CARL VOGT.

THE Helvetian Walhalla will shortly be enriched with a bust of Carl Vogt, for many years Professor of Natural History in the University of Geneva and one of the chief ornaments and attractions of the Swiss school. We have too recently put on record our appreciation of the nature-student and the man to warrant our recapitulating his many claims to the gratitude of his contemporaries. Suffice it to say that while the Darwinian hypothesis owes much to him for its early and widely diffused acceptance on the Continent, his

Digitized by Google

"Zoologische Briefe" takes rank with Liebig's "Chemische Briefe" for the enthusiastic votaries it has attracted to the subject it presents so winningly. Long, indeed, after it has been superseded by the researches it has inspired it continues, like Watson's "Practice of Physic" or Latham's "Lectures on Diseases of the Heart," to be read as a model of scientific style. The many-sided genius of Vogt coinciding with a peculiarly benevolent and "magnetic" personality imposed a difficult task on the sculptor who has attempted to embody their expression in marble; but M. Auguste de Niederhausern, the artist in question, has achieved a brilliant and a gratifying success. Vogt's energetic vitality, his vigilant intelligence, his profound, sympathetic humanity, brimming over in the kindliest humour—all speak from the plastic work of M. de Niederhausern and perpetuate the character as well as the lineaments of the great naturalist for all nations and for all times. So felicitously rendered is the citizen as well as the *savant* that his Genevese compatriots are already grudging its relegation to the vestibule of the University, and are pleading for its being placed in the open air on the Promenade des Bastions—a position for which its lordly dimensions peculiarly adapt it. Vogt, they maintain, belonged to the public even more than to the school, and while the vestibule of the University is undoubtedly the proper *locale* for celebrities of a purely academic type, his large and versatile personality claims a post in fitter keeping with compatriot homage than the "groves of Academe." The controversy is a kindly as well as an interesting one; but however it may be settled, science may congratulate herself on having in perpetuity the "animated bust" of one of her truest votaries—a presence, in Lord Beaconsfield's language, calculated "not only to commemorate, but to inspire."

PSEUDO-BULBAR PARALYSIS.

IN the last volume of the Clinical Society's Transactions Dr. Newton Pitt has given full clinical and pathological details of a striking case of this interesting form of disease. The patient when first seen was a man aged fifty-one, who at Christmas, 1892, had an attack of slight right-sided weakness without aphasia. The face was markedly affected and inability to close the right eye persisted. Two months later he had an attack in which numbness about his left hand and the left side of the face was noticed. He was also speechless, but in the course of a few hours his speech returned, but was again lost, and it returned and was lost several times in the course of a few hours. It finally was lost and remained permanently in abeyance. He was first seen about sixty hours after the attack; then his face was expressionless, he was unable to raise or move his lips, and he could not close the eyelids tightly, although they were closed during sleep. He was unable to protrude his tongue or to swallow anything. His limbs were weak on both sides, but the knee-jerks were brisk, that on the left side being the greater. There was no impairment of sensibility and no wasting or fibrillary twitching in the tongue or other muscles. The urine contained albumen. The patient was carefully fed with the tube and gradually improved, so that he was able to return home, taking a tube with him. After six months, however, he was readmitted suffering from ascites. He was tapped on two occasions, but he gradually became more feeble and died. At the necropsy two patches of softening were found, one on the right side extending above the lenticular nucleus, and below, lying on its inner and posterior part, extending into the middle of the posterior limb of the internal capsule; the other on the left side, occupying the middle of the posterior limb of the internal capsule and below extending into the posterior part of the lenticular nucleus. The cerebral arteries were distinctly atheromatous. This case, it will be seen, is an excellent example of what is known as pseudo-bulbar paralysis—a form of paralysis in which the symptoms closely simulate those of bulbar palsy, but in which the lesion does not affect the cells of the bulbar nuclei, but consists of some change on each side of the cerebrum. Attention has been directed to the condition in this country, chiefly by Dr. Hughlings Jackson and the late Dr. James Ross of Manchester, and typical examples of the condition have been recorded by these observers as well as by Dr. Barlow and others. The explanation that has been offered is that with a lesion occurring on each side of the cerebrum there are movements lost which a unilateral lesion can only abolish temporarily, and especially those so-called bilaterally associated movements the muscles for which are subserved by the nerves whose nuclei are situated in the bulb. Of these muscles the chief are the tongue, the muscles of deglutition and mastication, and the facial muscles. Dr. Pitt's case is one of the most complete illustrations of this morbid condition that has ever been published, and he is to be congratulated on the manner in which he has put it on record.

THE BATTLE OF THE CLUBS AT BRUSSELS.

THE Brussels clubs are now, as we mentioned last week, without medical officers, the whole twenty of them having resigned, and no one else being willing to take the vacated posts—which, by the way, are only worth £48 per annum—until well-to-do people are excluded. The club officials are much incensed against their quondam medical attendants, and although these latter are continuing to visit—as a matter of charity—all the club patients who were on their lists at the time of resignation, notice has been given that the clubs will pay a fee of 2 francs when a member calls in a medical man, provided the latter be not one of those who have resigned. It is in this petty spirit of retaliation that the clubs are carrying on the contest. A hope is generally expressed that the university professors will make a point of impressing on the students who are completing their courses the necessity of working in concert with the whole body of the profession by utterly refusing to accept any of the vacated posts.

A SPLINTER IN THE TYMPANUM.

WHATEVER excuses may be made for the practical joker, it is not without reason that he is commonly regarded by the subjects of his operations with a feeling of uneasiness and suspicion. In him the craving for amusement is all too masterful, too heedless of the wishes and even the safety of his neighbours. His intention, indeed, may not be mischievous, but as much cannot always be said of its consequences. The truth of these remarks has been sadly and strikingly illustrated by the details of a recent fatal occurrence at Tottenham. The facts in this case were the following. A provision dealer's traveller called at a public-house for refreshment and there fell asleep. An attendant noticing this proceeded to amuse himself, as others may have done under similar circumstances, by tickling the sleeper's ear with a wooden spill used as a pipe-light. The danger of such a proceeding might have suggested itself to any reasonable person, but in this instance it does not seem to have been thought of. A quick unconscious movement buried the wooden point in the drum of the ear, and fatal inflammation of the brain resulted. A jest with a sadder or a less expected termination was, perhaps, never practised. One cannot help mingling with a natural feeling of indignation something of pity for the unfortunate cause of this accident as well as for the immediate sufferer by it, and we may surely entertain a confident hope that the lesson of precaution so sharply

Digitized by Google

taught will not be forgotten. The history of punctured wounds of the tympanic membrane is not always as disastrous as in this case. We have here the history of a roughly inflicted wound, probably overlooked in its beginning and rapidly becoming a seat of septic absorption. We may gather from it a second moral—namely, the necessity of treating antiseptically and at once any injury at this site. So treated, wounds of the drum will often heal perfectly, while, on the other hand, a delay of a single day may result in lifelong deafness or worse. For the same reason every parent should view with anxious concern the dangerous but far too lightly regarded incident of earache with its associated inflammation in the ear-drum of a child.

BREATHING AND PHYSICAL DEVELOPMENT.

EVERYBODY breathes and many people breathe in quite a wrong manner. Medical men have known this for a long time, as have also teachers of singing, but it has never been clearly put before the public. This want is now supplied in a little work by Surgeon-Captain Hoper-Dixon, called, "The Art of Breathing as applied to Physical Development." It is the outcome of a lecture delivered by him before the Royal United Service Institution in March, 1894. He points out how the main respiratory muscle is the diaphragm and gives a number of simple rules and exercises for training the same. It is an important point, for a proper method of breathing means improved nutrition and consequently improved health. We await with interest Part II. of this unpretending little book, wherein the author proposes to treat the musical side of the question.

THE MODE OF DEATH FROM ELECTRIC SHOCK.

DR. J. MOUNT BLEYER of New York has advanced the view that death from electric shock is due to "dynamic apoplexy." He describes the post-mortem appearances in a criminal executed by electricity in whom the bloodvessels of the trunk and limbs were almost empty, while those of the head and neck were distended with blood. The violent muscular contractions produced by electric shock naturally tend to alter very considerably the distribution of the blood in the various parts of the body, and it is very probable that great cerebral engorgement, with hæmorrhages into the brain substance, may commonly occur in death from electric shock. The medical man who made the necropsy, however, would seem to overstate the case when he says that two quarts of blood escaped when the skull was opened. There is not room in the cranial cavity for that quantity. The immediate cause of death from electric shock is almost certainly due to stoppage of the heart, the injury to the brain here described not being an essential factor, though it may frequently coexist as a complication.

BACTERIOLOGICAL WORK IN CAIRO.

CAIRO has now a Professor of Bacteriology, who will shortly be provided by the Egyptian Government with a laboratory; but in the meantime Dr. Kaufmann has at his own expense set up a private laboratory in his house near the medical school. Here rabies inoculations were regularly carried on with virus obtained from Paris, Vienna, and Cairo itself, until the work was forcibly stopped by the summer heat destroying the virus and by the rabbits dying of an epidemic of coccidium oviforme. Some hundred examinations of false membrane have been made gratis for medical practitioners of all nationalities, about half of the cases proving to be diphtheritic. There is apparently no diphtheria in Cairo just now, and the general results of serum inoculation have been encouraging. Dr. Kaufmann and his assistant are also busily engaged in making an analysis of all drinking water in Egypt from the river, canals, wells, cisterns, and native filters, and of ice and of soda water. The native earthen filters are found to furnish a purer water when they have been used than when they are quite new. Cairo water taken direct from the Nile contains throughout the year from 2000 to 5000 microbes in one cubic centimetre. This compares very favourably with the water-supply (before filtration) of most European cities. The Cairo water is at its worst in June, when the Nile is lowest and is discoloured green by algæ, which are said to come from the Equatorial Lakes. This year the green water has been unusually evident, and has baffled the efforts of the water company by choking up the sand filter beds. Experiments are now being made to try to precipitate the colouring matter which appears in the Nile for three or four weeks every year. The soda water made in Cairo is said not to be above suspicion. The ice of the large town of Tantah was found to be extremely bad, and upon an official visit to the factory it was found that unfiltered water was partially used by the native workmen in preparing the ice. Analyses of the water supplied by the Cairo Water Company have been made every week or two by their desire, and it is to be hoped some day that an analytical control may be furnished every day. Such repeated analysis is obviously desirable, for the same filter-bed has been found during a few days to vary from under 50 microbes to more than 2000. However, as good results accruing from the bacteriological examinations already made, the company has agreed to separate their drainage-pipes from their intake-pipes, and also to deepen the filtering layer of their beds from eight inches to sixteen inches.

THE ASSOCIATION OF WORKERS IN ASYLUMS FOR THE INSANE.

THE inaugural meeting of this association was held on July 18th, under very favourable auspices, in the rooms of the Medical Society, Chandos-street. Its members, male and female, occupy ground apart from that of the popular and much-patronised hospital nurse, they are comparatively seldom brought into public notice, and it may be confidently hoped that one result of the movement now initiated will be to secure a more general recognition of the anxieties and responsibilities of asylum life. Sir Benjamin Ward Richardson presided and delivered an address, in the course of which he remarked that while hospital nursing had become a sort of profession during the last fifty years no commensurate improvements had been effected in the case of asylum attendants. Education and training raised the status and increased the usefulness of nurses, and this experience will no doubt be repeated when the same conditions are applied to attendants on the insane. Among the vice-presidents of the new association are the Earl and Countess of Arran, Cardinal Vaughan, and Sir William Broadbent. Dr. J. A. Wallis, one of the Lunacy Commissioners, also took part in the proceedings, and expressed his cordial sympathy with the objects of the meeting.

THE EAST LONDON WATER-SUPPLY.

THE state of matters in the East of London, owing to the scanty water-supply, is becoming very serious. The water company have for the last eighteen years or so been in the habit of giving a constant supply, and in consequence of this the sanitary authorities have wisely done away with domestic storage cisterns. The result of this is that now that the water company in exercise of their strict legal right have discontinued the constant supply owing to the drought the domestic supply is necessarily very insufficient. The house drains are not properly flushed, and consequently get blocked, and subsequently to this the death-rate from diarrhœa and the

Digitized by Google

number of infectious cases notified are rising with startling rapidity, so that on July 23rd inquests were held on the bodies of three infants, and in all three cases medical evidence was given that death arose from diarrhœa, and that the smells from the drains were most offensive. We believe we are correct in saying that the company are bound to supply a sufficiency for domestic purposes; *vide* Section 53 of the Waterworks Clauses Act of 1847: "Every owner and occupier of any dwelling-house or part of a dwelling-house within the limits of the special Act shall, when he has laid such communication pipes as aforesaid and paid or tendered the water-rate payable in respect thereof, according to the provisions of this and the special Act, be entitled to demand and receive from the undertakers a sufficient supply of water for his domestic purposes." The water in some districts supplied by the company is said to be "on" for two hours only out of the twenty-four. We contend that such things ought not to be. Flushing drains is of far greater importance than the watering of roads and public gardens, and we hope that steps will be taken to enable Mr. Kyffin of Hackney to state a case to the Superior Courts, as he obtained magisterial leave from Mr. Bushby to do so.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND CHOLERA MEDICINES.

THE public is still under the delusion that the Royal College of Physicians of London has prescribed for it in view of all cholera seasons and complaints, and some druggists perpetuate the delusion by having on their counters mixtures made up purporting to contain the precious ingredients once recommended for ready use in a time of panic. It is time this delusion was exploded, and the profession has a right to expect the assistance of druggists in the matter. Whether it is ever the duty of the College to publish a general prescription, even on the invitation of Government, is a fine ethical point which deserves a little more attention from the College than it has received. But of one thing there can be no doubt—that the particular prescription referred to is somewhat antiquated and no longer represents the most enlightened views of physicians as to the best way of treating cholera and choleraic disease of a milder type. Happily, in the present year the element of panic does not exist; but, even so, there are right and wrong ways of treating choleraic attacks, and it is certainly true that among the wrong ways is the employment of a stereotyped prescription for general use.

FRONTAL TUMOUR WITH PSYCHICAL SYMPTOMS.

IN a recent number of the *Revue de Médecine* Dr. Lepine records the case of a woman aged forty-four, without a previous history of any significance, who had one night a convulsive seizure, followed by loss of consciousness and subsequently orbital headache, vertigo, and noises in the ears. On admission to hospital there was some psychical dulness, difficulty in walking, apparently from some impairment of equilibration, sometimes a tendency to retropulsion, and slow speech. Next day she had an attack in which she became comatose, with the head and eyes turned to the right. The pulse was slow, but unconsciousness only lasted a day. It was succeeded by a month of a condition similar to that in which the patient was on her admission. Then an attack of unconsciousness succeeded, with deviation of the head and eyes to the left and left facial paralysis. On emerging from the unconsciousness a curious psychical change was manifest. She had lost all recollection that her husband was dead (he had died seven years before), and she fancied that the patient in the next bed was her cousin. There was also left hemiopia. Another attack of unconsciousness was experienced, and this was followed by death. At the necropsy the pia mater and dura mater were found adherent at the anterior part of the right frontal lobe, and at this part a gummatous growth was found as big as a walnut. In the longitudinal fissure also on the left frontal lobe a little in front of the genu of the corpus callosum a smaller and apparently more recent gumma was found. No other appreciable changes in the cerebrum were discovered. The presence of psychical symptoms in this case is very interesting, especially in association with a morbid condition of the frontal lobes.

WE deeply regret if we have given the impression in a recent annotation upon self-poisoning by chloroform that the death of a distinguished young medical man, Dr. T. G. Sloan, was anything but the result of an accident. We understand that the statement published elsewhere that Dr. Sloan's face was found buried in his handkerchief is incorrect, and that his use of chloroform was not habitual. We sympathise very heartily with the Rev. John Sloan, the unfortunate young man's father, in the terrible loss that he has sustained, and deplore the fact that any misinterpretation should have added to his grief.

THE Executive Committee of the General Medical Council met on Monday last to consider the conveyance to the Council of 16, Hanover-square, in accordance with the resolutions passed at a recent meeting. Estimates for the proposed alterations were considered, and the lowest tender accepted, and it was decided to submit the plans for warming, lighting, and ventilating to Dr. Thorne Thorne and Mr. Teale.

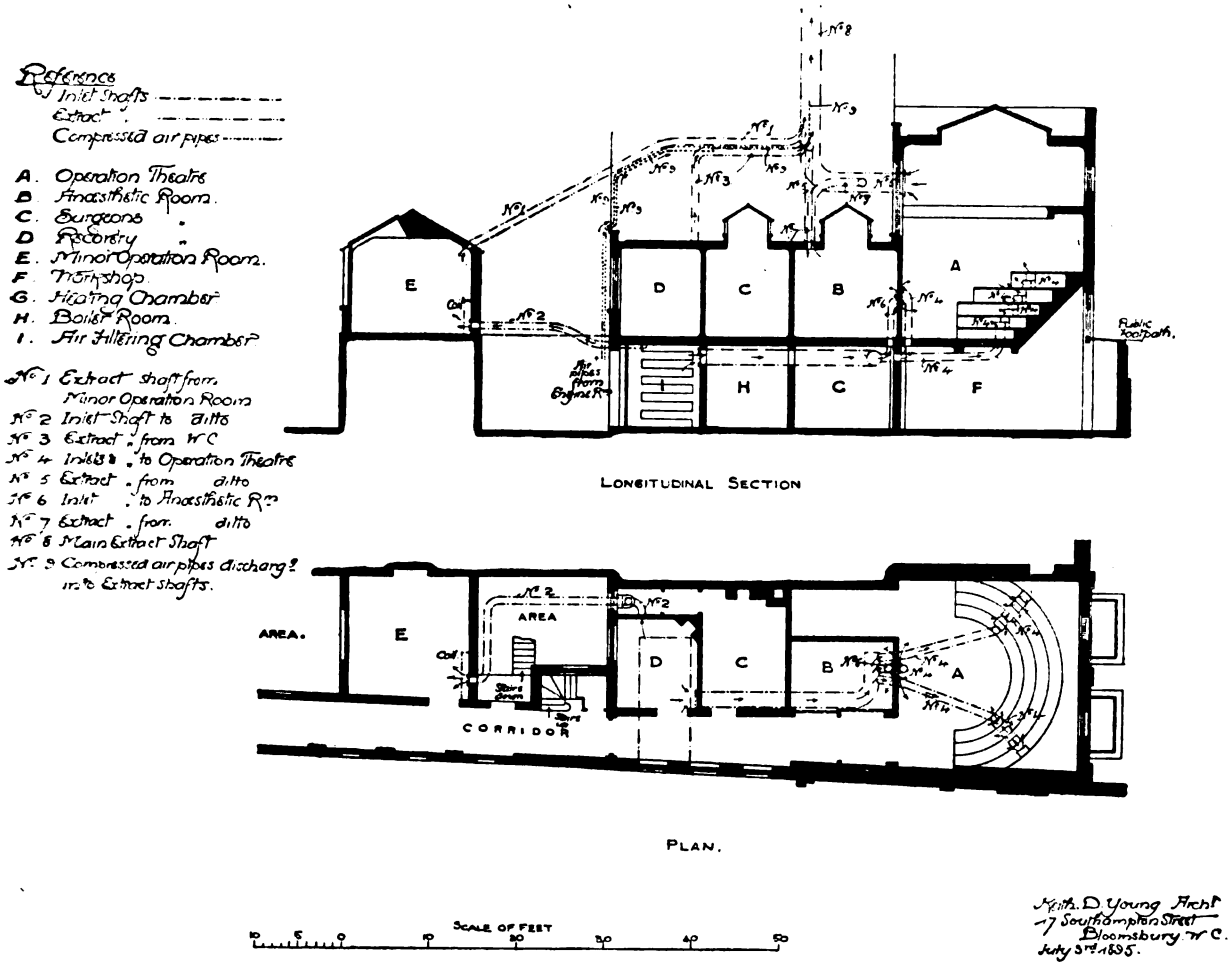
BY the death of the venerable Professor Charles Cardale Babington, F.R.S., which occurred on Monday last, the University of Cambridge loses one of its best known and most popular, able, and respected teachers, and the scientific world a well-known botanist and antiquarian.

THE MIDDLESEX HOSPITAL.

NEW OPERATION THEATRE, &c.

THE new building comprises a large theatre, a room for the administration of anæsthetics, a surgeon's room, recovery room, and a small theatre for special operations, all on the ground floor; also a large work room for the instrument man and a boiler-house and rooms for the ventilating and heating apparatus in the basement.

The large theatre has accommodation for about 130 students in semicircular tiers of benches formed of teak and approached by a staircase outside the theatre corridor. This staircase gives access to a gallery which runs round three sides of the theatre, whence two teak staircases lead down to the top tier of staging. The walls of the theatre are lined with glazed tiles, the lower part of which are green and the upper part buff. The floor is of marble terrazzo, of which material also the floors of the gallery and corridor are formed. In a recess on one side of the theatre are two lavatory basins, an enamelled slate shelf for carrying the electric apparatus for boiling water, a sink for cleaning instruments, and a slop sink; a cupboard for dressings and a lift to the basement for conveying instruments, &c., up and down. In this recess also are four sets of plate-glass shelves carried on specially designed brass brackets.



On the wall at the back of the operation table are two glass black-boards let in flush with the tiles. The instrument case, made entirely of glass and brass, stands in the recess to the left of the table. Facing this are two porcelain sinks for washing sponges, with the small wringer fixed between. Above these sinks is a glass shelf, on which stand the jars containing antiseptic solutions. All the pipes supplying the sinks are of copper and the taps and valves of brass. The glass jars for irrigation are fixed to the ceiling of the gallery

Digitized by Google

to teak blocks let into the concrete. In the centre of the lowest tier of staging is a glass case containing electric plugs for cauteries, hand-lamps, &c.

The theatre is lighted by seven single-light pendants, containing one 16 candle-power lamp each and an adjustable pendant for the operation table, which travels on a brass rod fitted from one side of the gallery to the other. The anæsthetic room has a dado of glazed tiles above, while the walls provide the necessary warmth in cold weather. In each inlet trunk and also in each outlet trunk a pipe conveying compressed air is fixed and the air is discharged through a nozzle into the trunk. The high velocity of the air thus discharged causes the air in the trunk to move in the direction of the nozzle, and it is found that the air of the large theatre can be entirely renewed with no perceptible draught between ten and eleven times in the hour.

The Middlesex Hospital Mortimer Street W.
New Operation Theatre.

are painted and varnished. The door to this room, which is of oak, is hung on wheels at the top, and slides into a recess in order to give ample room for wheeling the ambulance in and out. The floor is of teak. The surgeon's room has painted walls and a teak floor.

The smaller operating theatre has its walls lined with tiles and a terrazzo floor similar to the large theatre. There is a large vertical window facing north with a roof-light over it. A lavatory basin, a sink, and glass shelves, similar to those in the large theatre, are provided here. The corridor of access is paved with terrazzo, and the walls and ceiling are lined with glazed tiles. The large and small theatre and the anæsthetic-room are warmed and ventilated partly by direct radiation from hot-water coils and partly by a mechanical system, the motive power of which is compressed air. The whole of the air which is to be admitted into these rooms is first passed through a filter-chamber containing a series of trays filled with cotton-wool, with, at the entrance, a vertical screen of hemp, over which a water-spray is projected to intercept the coarser particles. From this chamber the air passes by ducts into a room in which is a very large and powerful series of hot-water coils, which

An exhaust shaft only is provided to the w.c. attached to the surgeons' room, in order to guard against the possibility of air passing from the w.c. towards the theatre. The inlet tubes in the theatre and anæsthetic room are formed of copper, and have specially devised mouthpieces for spreading the air in all directions.

It will be seen that this addition to the hospital leaves nothing to be desired from the most modern point of view.

THE PERNICIOUS FEVERS OF EASTERN AFRICA.

STAFF-SURGEON-MAJOR STEUDEL, of the German army of occupation in Eastern Africa, who has been for some time past in medical charge of the hospital at Bagamoyo, has written a most interesting paper on the bilious hæmaturic fevers of the locality, which has been published in part by the authorities at Berlin. In twelve cases he made an

Digitized by Google

examination of the blood by means of Fleischl's hæmometer, and found that the amount of hæmoglobin present oscillated between 50 and 21 per cent. of the normal standard. In two other cases the quantity was too small to be determined by the instrument, but it was estimated by the observer at not more than 5 and 8 per cent. respectively. He lays stress upon the prognostic value of hæmatological examinations, and furnishes details regarding two patients with a deficiency of hæmoglobin in their blood in whom bilious fever subsequently showed itself on several occasions when their ordinary mode of life underwent a change for the worse.

It seems only reasonable to conclude that a systematic use of the hæmometer cannot but render great service in the detection of the incipient stage of a disease which is invariably attended by more or less destruction of the red corpuscles of the blood. Staff-Surgeon-Major Steudel looks on the diminution of hæmoglobin as a certain index of latent or incipient malaria, and is satisfied that this important sign manifests itself long before the more salient symptoms become apparent. As long as the impoverishment continues slight the sufferer can be restored by appropriate treatment on the spot, but as soon as it passes certain limits he should at once be invalided to Europe, or at all events sent to a sanatorium. The means thus furnished for unmasking the insidious enemy while it is still comparatively impotent, and before it has had time to acquire the firm hold on the patient's constitution which it subsequently manifests, should enable the medical officer to save many a valuable life that otherwise would be sacrificed to the curse of Africa. In this connexion it is impossible to avoid calling to mind the untimely deaths of the two distinguished brothers cut off by African fever in well-nigh the bloom of their youth. Perchance if the hæmometer had been used, as the German surgeon suggests, the sacrifice of the Portals might have been averted.

In one case, where the hæmoglobin was reduced to less than 8 per cent. of the usual amount, Staff-Surgeon-Major Steudel had recourse to transfusion of blood with conspicuous success, the supply of vital fluid being furnished by a young negro. Almost immediately the percentage of corpuscles rose to 20, and eventually the patient made a good recovery. Transfusion in paludism does not seem to have been often essayed, and yet in the rare cases that are recorded the effects of fresh blood are said to be highly satisfactory. According to the Italian school, the physiological solution of chloride of sodium gives just as good results as the arm-to-arm procedure, if not better, but exact data with regard to the entire subject are still wanting. With reference to substitutes for human blood in transfusion, an anonymous writer in the *Archives de Médecine Navale et Coloniale* warns prospective transfusers against making a trial of the blood of mammifers for intravenous injection, the effects being disastrous to the integrity of the remaining red corpuscles. In some instances where the experiment was tried aggravation of the symptoms ensued, accompanied for the most part by hæmaturia. The same writer recommends venesection before transfusion, in order to free the system from a portion of the toxic products of the disintegrated hæmoglobin. Venesection alone without subsequent transfusion has been tried in the convulsive form of impaludism, and apparently with good effects. Kelsch and Kiener relate a case[1] in which Dr. Borius was satisfied that he had saved the life of a patient who was well-nigh *in extremis* by a copious depletory bleeding; but here, too, more detailed information is a desideratum.

In severe cases of paludal fever Staff-Surgeon-Major Steudel gives as much as ten grammes of quinine (154 grains) for a dose, the results of this somewhat heroic medication being extremely brilliant, not a single patient so treated having died. In the opinion of many medical men practising in malarious regions quinine in large doses is apt to provoke hæmaturia. This view is almost universally prevalent amongst Grecian practitioners, but the careful observations of the German surgeon would seem to prove the contrary. As a prophylactic he gives the drug in doses of from twelve to fifteen grains once a week in fair weather and twice a week during the rains.

There is one point bearing on the etiology of paludism which receives some elucidation in the Bagamoyo record, and is both novel and interesting. Bilious fever seldom or never attacks men when they are on the march or engaged in any occupation necessitating hard work. The disease waits, as it were, until they are enjoying an unguarded repose before pouncing down upon them. In the opinion of Staff-Surgeon-Major Steudel the reason of this is that so long as the body is maintained in a state of activity the products of disintegration are completely eliminated as soon as they are formed, whereas during inactivity the blood becomes more or less charged with detritus, which serves as nidus for the paludal poison.

Finally, Staff-Surgeon-Major Steudel lays down the following practical rules. Every man designated for service in Eastern Africa should be thoroughly examined as to his constitutional fitness. He should be in perfect condition as regards his heart, stomach, and intestinal tract, and should be quite free from all traces of anæmia and neurasthenia. Ear affections, interfering with the administration of quinine, should likewise be considered prohibitive, and so should the intolerance of that drug which constitutes an idiosyncrasy with some people.

MEDICAL TRIALS.

COUNTY COURTS AND MIDWIFERY ENGAGEMENTS.

AT the Holywell (Flintshire) County Court on July 16th a case which raised a point hitherto undecided was heard, in which Mr. J. William Parry, a physician and surgeon practising at Bagillt, sued a man named John Venables Price for £2 8*s.*, balance of account and damages for breach of contract. Mr. H. T. Smith, solicitor, appeared for the plaintiff.

Mr. Parry stated that defendant owed him 6*s.* balance of account rendered. In July, 1893, defendant specially engaged him to attend his wife at her approaching confinement, it being agreed between them that plaintiff was to attend in any case, and not merely in the case of an emergency arising. Defendant said he wished him to attend his wife without a midwife, and plaintiff entered it in his book as an engagement, and held himself in readiness to attend when required. Defendant's wife was duly confined, but plaintiff was not called in. In April last defendant again came to engage him for a similar purpose. Plaintiff told him he had done wrong in not calling him in on the previous occasion, and said to him, "Is it right on this occasion?" and he replied that it was. Notwithstanding this plaintiff was not called in at the confinement. Plaintiff had brought this case as a test case in order to put a stop to a practice which was getting very common in Bagillt.

His Honour considered that the plaintiff had waived his claim to the £1 1*s.* for July, 1893.

Defendant stated that it was the custom to pay the medical man half a guinea "if you spoke in time," but a guinea if you called him in suddenly.

His Honour said a bargain was a bargain. Defendant had engaged the medical man to attend his wife, and if he had not come when called he would have found fault with him. He should give a verdict for plaintiff for half a guinea, together with the 6*s.* balance of account.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Committee of the Association of Fellows of the Royal College of Surgeons of England was held at 101, Harley-street, W., on July 17th, at 5.30 P.M. The minutes of the last meeting were read and confirmed. Mr. Percy Dunn, the hon. secretary, drew attention to the result of the election of members of Council at the College on the 4th inst., and pointed out that two of the candidates supported by the Association had been successful. A vote of thanks was unanimously passed to Mr. A. T. Norton for representing the Association at the election.

The Hon. Secretary then read the following letter:—

Royal College of Surgeons of England, Lincoln's-inn-fields, London, W.C., 15th day of July, 1895.

DEAR SIR,—The attention of the President has been directed to THE LANCET of the 13th instant, in which are printed the alterations in the charters and by-laws of the College proposed by the "Association of Fellows," and in which a change has been made in paragraph 3 thereof, of which no notice has been received at the College. I am

Digitized by Google

therefore desired to inquire whether this change is to be understood to have been adopted by the Association. I am at the same time to express the surprise of the President that the proposals of the Association, which are still under the consideration of the Committee of the Council appointed to report thereon, should at this stage have been published in a public journal.

I am, Dear Sir, yours faithfully,

H. Percy Dunn, Esq. EDWARD TRIMMER, Secretary.

After some discussion the Hon. Secretary was instructed to forward to the Secretary of the College the following reply :—

54, Wimpole-street, July 17th, 1875.

DEAR SIR,—Your letter of the 15th inst. was read at a meeting of the Committee of the Association of Fellows held this afternoon, and I am directed to inform you that the amended Clause 3, published in THE LANCET, was not inserted either with the sanction or knowledge of the committee. Nevertheless, I am instructed to say that the amendment itself meets with the approval of the committee, and accordingly the committee would wish that Clause 3 should stand as follows:—"That no alteration in the constitution or external relations of the College shall be effected without the body corporate being convened to discuss such proposed alteration." While regretting that this amended clause should have appeared in THE LANCET before it had been officially communicated to the College, the committee desire it to be understood that they have always courted the fullest publicity for their proceedings, and for this reason it has been, and still is, their rule to sanction the earliest publication of them in the medical journals.

I am, dear Sir, yours faithfully,

H. PERCY DUNN, Hon. Sec.

The proceedings at the half-yearly meeting of the Fellows at the College were then discussed, and attention was drawn to the fact that the President had declared the meeting closed without affording to the Fellows any opportunity of discussing the business which appeared on the agenda. This appeared to the Committee to be of such importance that the following resolution was proposed, seconded, and unanimously passed :

"That the attention of the President and Council of the Royal College of Surgeons be drawn to the fact that the half-yearly meeting of Fellows on the 4th inst. was closed without any discussion being possible in respect to the business on the agenda; and that in the opinion of the Committee of the Association of Fellows such a mode of conducting these meetings would be destructive of the privileges conceded by the Council to the Fellows, and would render the meetings nugatory." It was also agreed that a copy of the foregoing resolution should be forwarded to the secretary of the College with a request that it should be laid before the Council at the next meeting.

It was resolved that the annual general meeting of the Association should take place in November at or about the date fixed for the annual general meeting of Fellows and Members.

This concluded the business of the meeting and the committee adjourned.

THE ROYAL FREE HOSPITAL.

ON Monday, July 22nd, the Prince and Princess of Wales, accompanied by the Princesses Victoria and Maud, visited the Royal Free Hospital for the purpose of opening the new front buildings, which complete the reconstruction of the hospital. The cost of the new buildings, reconstruction of the drainage system, and other necessary improvements has been about £30,000, and accommodation for 160 beds is now provided, with every convenience for the treatment of the sick poor.

Their Royal Highnesses arrived at the hospital shortly after one o'clock, and were received by the Earl of Lathom and the reception committee.

The Earl of Lathom read an address of welcome, in which it was stated that the Royal Free Hospital was founded by the late Dr. William Marsden in the year 1828, and was the first hospital in the metropolis to admit the sick poor without letters of recommendation. Since its foundation its benefits had been extended to more than two millions of patients, who claimed and obtained its aid by reason only of their poverty and suffering. It was the only general hospital in London which had opened its doors to female medical students, and for the past eighteen years it had afforded means of clinical instruction to the students of the London School of Medicine for Women, which now had 150 students. In the year 1842 the hospital was removed to its present site. The north side was rebuilt in 1855 by the Freemasons of England as a memorial to the late Duke of Sussex, and in 1877 the south side was erected and named the "Victoria Wing," in honour of Her Most Gracious Majesty the Queen, who, shortly after her accession to the throne, became its patron, and ordered that the institution should be called the Royal Free Hospital. The erection of the new front completed the work of reconstruction commenced forty-three years since, and the hospital was now thoroughly equipped in every department for carrying on its beneficent work. The new front building was to be called the "Alexandra Building," in commemoration of the day's proceedings.

The Princess of Wales having received a gold key of the new front entrance,

The Prince of Wales said :—"Ladies and Gentlemen, In the name of the Princess, and in my own, I beg to tender Lord Lathom our thanks for the address we have just heard. The Princess desires me particularly to express the great pleasure it gives her to be here to-day and to inaugurate the new wing, which will complete this great hospital. As so many members of my family have been connected with this institution, it is, perhaps, an appropriate occasion for us to be here to-day. I cannot forget that King George IV. and King William IV. were patrons, and the Duchess of Kent and the Queen, before she came to the throne, were also patrons, and that Her Majesty has ever since then taken a most active interest in the prosperity of this institution. I am glad to think that I myself have been connected with this institution since 1863 as vice-patron. I thank you once more for your kind reception to-day, and assure you that we are most glad to come among you, and wish prosperity and success to this excellent hospital. The Princess now desires me to say that she declares the new wing open."

Prayers were then offered by the Rev. C. J. Parker, the chaplain, and the Princess of Wales received purses in aid of the building fund.

In the absence of Sir Gainsford Bruce, Mr. Burt, in a complimentary and gracefully delivered speech, thanked their Royal Highnesses for their presence, remarking that 2000 years ago Alexander the Great offered the citizens of Ephesus all the spoils of his Eastern campaign if they would allow him to have his name placed on the Temple. The citizens were proud and self-sufficient, and refused. Those present had for forty years been building up their temple, which was not so glorious and magnificent as the Temple of Diana, but which was raised to the glory of God and for the healing of the sick, and they were glad to be able to place the name of Alexandra on the final section of the hospital in remembrance of a Royal, gentle, and gracious Princess, whose nobility of character, kindness of heart, and tender sympathy for all the poor, sick, and suffering were known to all the world.

After visiting several of the wards and other parts of the hospital their Royal Highnesses left by the main entrance amidst cheers from the large crowd which had assembled outside.

THE MIDWIVES REGISTRATION ASSOCIATION.

WE have been desired by the secretaries of this Association to insert the following letter, that it may reach the eyes of those whom their notices have perhaps failed to reach :—

"DEAR SIR,—If you are in sympathy with the principle of registration of midwives please attend the meeting in Exeter Hall on Tuesday, July 30th, at 2.30, to vote, or to speak and vote, against the motion standing in the name of Mr. Lawson Tait, and subjoined, which will be taken in the discussion on the report of the Council of the British Medical Association produced to that meeting.

"Your presence is urgently requested.

"Yours truly,

"R. BOXALL, M.D.,

"F. R. HUMPHREYS,

"Honorary Secretaries, Midwives Registration Association."

Mr. Lawson Tait's motion to be seconded by Mr. Colin Campbell :—

"That we, the Members of the British Medical Association, while anxious to improve the training and supervision, and, if need be, to support a practical scheme for the registration of medical, surgical, and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical or surgical or midwifery practitioners other than those recognised under the Medical Act, 1886, as now existing. We protest against the Midwives Registration Bill because it proposes to establish a class of midwifery practitioners who would be very incompletely trained in midwifery, and entirely uninstructed in medicine, surgery and pharmacy—a matter of supreme importance in midwifery practice. We, therefore, instruct the Council and the Parliamentary Bills Committee to use every means to oppose

Digitized by Google

any Bill which proposes to give to persons registered under it power to conduct on their sole and independent responsibility any midwifery practice without the guarantee of a complete curriculum and qualification. That this Association recommends a sum not exceeding £1000 be expended for the purpose of opposing any such Bill."

THE SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE COUNCIL OF THE COLLEGE.

As stated in our last issue the Council has appointed the same committee which recently received a deputation of Fellows on the subject of the proposed changes in the Charters to receive a deputation of Members with reference thereto. The deputation will attend to-day (Friday) and the following are the amendments to the Charters which the Society of Members will advocate:—

1. That no alterations in the constitution and external relations of the College shall be effected without the consent of the corporation convened to discuss such alterations.

2. That a statutory annual general meeting be held of the corporation, to which the Council shall present a report of its proceedings during the past year, together with a duly audited account of the income and expenditure of the College; this report must be submitted for the approval of the meeting and formally adopted.

3. That the number of the Council be increased to thirty-two, and that eight of these shall be Members (who are not also Fellows) and shall be elected by the Members only.

4. Provided that no Member who has not been a Member for twenty years shall be eligible for a seat on the Council.

5. That the same by-laws and regulations which are at present in force for the election and admission of Fellows to the Council shall govern the election and admission of Members, the word "Member" being substituted for "Fellow" throughout.

6. That of the eight members first elected on the Council, two shall retire annually in rotation, commencing with those two who have received the lowest number of votes, but that these shall be immediately eligible for re-election; after the end of the fourth year, when the eight members first elected on the Council shall all have been retired, the two members to go out of office annually shall be those two who have been longest on the Council without re-election.

The deputation will further support the election of the President, as at present, from and by the enlarged Council.

We are informed that the committee of the society regard the first three clauses as the essentials of their proposal; and that they bring forward the remainder, as the absence of any detailed scheme has on previous occasions been made a subject of complaint.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Birmingham Urban Sanitary District.—Birmingham ranks in the matter of population as the fourth largest town in England including London, the only two provincial towns exceeding it being Manchester and Liverpool. Estimated to the middle of 1894 the population of Birmingham amounted to 492,301, and the number of persons per acre to 38·7. Average density of population goes, of course, for very little without detailed information as to local distribution, as one area may be much overcrowded and another almost unpopulated. It may be mentioned, however, that the density of population in Liverpool amounts to 97·3, in London to 58·2, and in Manchester to 40·3 persons per acre. Dr. Alfred Hill has been able in his current annual report to supply death-rates for the several wards in the city, the highest (St. Mary's) being 26·3 and the lowest (Edgbaston and Harborough) 13·4 per 1000. The infantile mortality for the year was 164 per 1000 births, as against rates of 179 and 174 for Liverpool and Nottingham respectively. The zymotic death-rate for 1894 was 2·4 per 1000, a rate comparing favourably with the average of the last eight years; but in the matter of enteric fever the report tells us that the cases notified were more numerous than in any year since the introduction of notification. As bearing upon this question it may be remarked that more than half the closet accommodation of Birmingham is on the conservancy system, and Dr. Hill estimates that the incidence of typhoid fever was nearly half as great again upon houses provided with pan-privies as upon those provided with water-closets. There were no less than 2074 cases of small-pox notified in Birmingham during 1894, figures that show that the epidemic was much more severe than that of 1883–84, but less so than the one culminating in 1874. Coming now to the question of vaccination, Dr. Hill reports that of the 2074 cases notified, 1769 were vaccinated, 224 unvaccinated, and 81 doubtful as to vaccination. The following table shows the fatality-rate among the three classes:—

	No. of cases.	No. of deaths.	Proportion of deaths to cases.
Vaccinated	1769	77	4·4 per cent.
Unvaccinated	224	75	33·5 ,, ,,
Doubtful	81	13	16·0 ,, ,,

We also furnish for the information of our readers the accompanying table taken from Dr. Hill's report, which shows the incidence of the disease on the several age periods. Dr. Hill observes that he has not calculated the percentages on less than 10 cases. The table in the main explains itself, and it will be seen that among the 241 vaccinated patients under fifteen only 1 died, a boy whose attack was complicated with scarlet fever; while among the 152 unvaccinated cases at the same age periods no less than 51 died. In other words, the fatality-rate among the vaccinated was 0·5 per cent., that among the unvaccinated 33 per cent. In face of figures such as these, showing the enormous protection afforded to our infant population by vaccination, who would wish to be responsible either directly or indirectly for the abolition of compulsory vaccination, unless, indeed, it be considered desirable to reduce the infant population?—

Ages.	Vaccinated.			Unvaccinated.			Doubtful.		
	Cases.	Deaths.	Case mortality per cent.	Cases.	Deaths.	Case mortality per cent.	Cases.	Deaths.	Case mortality per cent.
Under 1 year...	0	0	—	41	32	78	0	0	—
Between 1 and 5 years	5	0	—	38	13	34	6	0	—
Between 5 and 15 years	236	1	0	73	6	8	14	1	7
Between 15 and 25 years	707	13	2	38	8	21	19	1	5
Between 25 and 45 years	689	52	8	25	12	48	28	8	29
Between 45 and 65 years	119	9	8	7	2	—	12	2	17
65 years and upwards	13	2	15	2	2	—	2	1	—

Salford Urban Sanitary District.—This important county borough has a population, as estimated to the middle of 1894, of 205,828. The mean density of the population is equal to 39 8 persons per acre, but the ward density varies from 116 4 in Greengate to 21·9 in Pendleton. The general death-rate of the district for 1894 was 20·9 per 1000, a rate lower than any recorded during the last thirty-four years. In respect to district mortality rates there was an all-round fall on those for 1893, that for Greengate being 26·4 per 1000, and that for Broughton 16·5. There was in 1894 a very material reduction in the infantile mortality—i.e, it was but 174 per 1000 births, as compared with a quinquennial average of 194. An unsatisfactory feature in the birth-rate was a rise in the percentage of illegitimate births. As regards zymotic diseases, it is gratifying to note a decline in the mortality from diphtheria. Mr. Charles Paget refers in his report with much satisfaction to the fact that a greatly increased percentage of infectious disease cases seek isolation in hospital as compared with former years. Among the cases sent into hospital during the year under review were 31 in which the diagnosis was erroneous, and in this connexion it is very interesting to find that the percentage of erroneous diagnoses ranged from 8 6 in Greengate district to *nil* in the Broughton district. There were 35 cases of small-pox notified during 1894, the fatality rate among the 4 unvaccinated cases being 25 per

Digitized by Google

cent., that among the doubtfully vaccinated cases 50 per cent., and that among the 29 vaccinated cases *nil*. A model lodging-house has been completed in Salford, and is proving, Mr. Paget reports, a great success. Male lodgers only are admitted, and each is provided with a separate cubicle. The charges are 4*d*. and 5*d*. per night, or 2*s*. and 2*s*. 6*d*. per week. Only persons of "cleanly and respectable appearance and free from filth and disease" are admitted. In an appendix to Mr. Paget's report is a copy of the general regulations appertaining to sanitary inspectors, and we notice with satisfaction the following paragraph: "The Health Committee wish it to be distinctly understood that every inspector is expected to do his duty with absolute impartiality. The committee undertake that no inspector shall suffer in any way from discharging his duty or reporting defects in property belonging to persons of position and influence."

Newcastle Urban Sanitary District.—In connexion with the relative incidence of enteric fever on households provided with water-closets on the one hand and pails on the other, Dr. Armstrong reports that during 1893 there were 0·3 per cent. of the former houses invaded, as against 0·6 per cent. of the latter. Commenting upon the number of deaths from scarlet fever during 1894 Dr. Armstrong observes that the total mortality from this disease at the present time is almost insignificant as compared with the returns of some former epidemic years, the disease having, he remarks, during the last quarter of the century been undergoing a gradual change of type from severe to mild. Instead of a fatality rate of 25 or 30 per cent., which was occasionally observed in former years, there was during 1894 one of but 3·3 per cent. It is probable, however, that together with a change of type in the disease there have been, owing partly to notification and partly to a better knowledge of the natural history of the disease, more mild cases brought to light.

Norwich Urban Sanitary District.—During the first three weeks of 1894 the general death-rate of Norwich amounted respectively to 37·5, 61·0, and 43·0 per 1000, rates which led the Local Government Board to require from Dr. Cooper-Pattin a special report. He considered that Norwich contained more inhabitants at and over sixty-five years of age han any other city or town of the same population, and the excessive death-rate he regards as being due to the effect of the influenza and the sudden variation of temperature which took place during the weeks in question. In dealing with the influences favouring the spread of scarlet fever Dr. Cooper-Pattin records that the headmistress of a certain school, who had contracted scarlet fever from one of her pupils and was isolated in the fever hospital, occupied her time to such good purpose as to become quite an adept at the diagnosis of the disease; and since her return to the school her freshly acquired knowledge has been turned to excellent account. The Norwich Fever Hospital accommodation is, it appears, insufficient for the demands likely to be made upon it, and in advising the enlargement of the building Dr. Cooper-Pattin observes that without the capacity for quickly extending its resources a fever hospital cannot do its best work. There is no provision for cases of enteric fever in the Norwich Fever Hospital, and in advocating such provision he states that he has been most painfully impressed by the unfavourable surroundings amid which he has found typhoid fever being treated in the dwellings of the poor. As he observes, "Within the cramped and narrow limits of a poor man's home typhoid fever becomes easily transferable from person to person." Notification has, he reports, brought to light many insanitary conditions, and he records that during his period of office no less than 1000 houses have had their sink-pipes disconnected with the sewers. In 1893 an offer was made to gratuitously disinfect the rooms &c. in any case where a tuberculous patient had resided, but it speaks badly for the appreciation by the public of this offer to have to record that during 1894 in only five instances was advantage taken of it. In the appendix to his report Dr. Cooper-Pattin inserts a paper on the Tuberculoses in England and Wales, with special reference to their prophylaxis, which was contributed to the State Medicine Section of the Eighth International Congress of Hygiene and Demography held at Budapest last year.

Derby Urban Sanitary District.—Mr. W. Iliffe records in his annual report an instance of the difficulty which may be encountered in enforcing dual notification. Under the Derby Improvement Act, 1879, it is enacted that the person having control of the building in which a case of infectious disease occurs shall, "as soon as he shall become aware of" the existence of the case, notify it to the medical officer of health. In the instance in question it was proved that the mother had acknowledged her child to have had a rash and sore throat, and that she thought it might have been scarlet fever; a possibility which she had apparently discussed with a neighbour whose child subsequently developed scarlet fever and died. When Mr. Iliffe visited the house he found the child soaking its legs and feet in hot water—in order, the mother admitted, to hasten the peeling, which at the time seems to have been profuse. In spite of all the foregoing facts, the magistrates were not satisfied that the mother had "become aware" of the existence of the disease. Mr. Iliffe thinks that the Derby Improvement Act requires amendment, and he suggests that instead of the words "so soon as he shall become aware of," the words "if he have reasonable cause to suspect" be substituted. There were 104 cases of enteric fever notified in Derby during 1894, the cases occurring in eighty-nine houses. In eighty houses there were single cases, in six 2, in one 3, in one 4, and in one 5. Mr. Iliffe regards the comparatively few houses in which the disease spread as an instance of the care which was taken with regard to the carrying out of the printed directions left at every house in which a case was reported. The dates on which the second and subsequent cases occurred in houses invaded by multiple attacks is not furnished, but it is to be inferred that the necessary incubation periods intervened. There always seems to us, however, to be a difficulty in eliminating a common source of infection in cases such as those referred to. The general death-rate of Derby for 1894 was 15 0 per 1000, the lowest yet recorded, and a rate which for the year in question places Derby third on the list of the large towns, Croydon having a rate of 13·2 and Leicester one of 14 7.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6267 births and 4446 deaths were registered during the week ending July 20th. The annual rate of mortality in these towns, which had increased in the five preceding weeks from 15·4 to 19·9 per 1000, further rose last week to 21·9. In London the rate was equal to 23·7 per 1000, while it averaged 20 6 in the thirty-two provincial towns. The lowest rates in these towns were 10·5 in Brighton, 10·9 in Croydon, 11·7 in Halifax, 12·1 in Huddersfield, and 12·3 in Bristol; the highest rates were 25·9 in Preston, 26·2 in Leeds, 26 8 in Norwich, 27·5 in Salford, and 30·3 in Liverpool. The 4446 deaths included 1137 which were referred to the principal zymotic diseases, against 665 and 877 in the two preceding weeks; of these, 798 resulted from diarrhœa, 138 from measles, 72 from whooping-cough, 67 from diphtheria, 39 from scarlet fever, 23 from "fever" (prinpally enteric), and not one from small-pox. No fatal case of any of these diseases occurred last week in Huddersfield; in the other towns they caused the lowest death-rates in Bristol, Portsmouth, Halifax, and Blackburn, and the highest rates in Salford, Leicester, Liverpool, Leeds, and Preston. The greatest mortality from measles occurred in Plymouth, Manchester, Newcastle-upon-Tyne, and West Ham; from whooping-cough in Birkenhead, Liverpool, and Gateshead; and from diarrhœa in Liverpool, Bolton, Bradford, Salford, Leicester, Leeds, and Preston. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 67 deaths from diphtheria included 39 in London, 5 in West Ham, 5 in Birmingham, and 3 in Cardiff. No death from small-pox was registered either in London or in any of the thirty-two large provincial towns. There were 89 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, July 20th, against 34, 42, and 71 at the end of the three preceding weeks; 23 new cases were admitted during the week, against 25, 17, and 36 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2267, against 1894, 2044, and 2241 on the three preceding Saturdays; 220 new cases were admitted during the week, against 319, 311, and 342 in the three preceding weeks. The deaths referred to

Digitized by Google

diseases of the respiratory organs in London, which had been 160 and 187 in the two preceding weeks, further rose to 193 last week, and were 14 above the corrected average. The causes of 54, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Nottingham, Bradford, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Brighton, Birmingham, Liverpool, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 19·2 to 20·3 per 1000, declined again to 18·2 during the week ending July 20th, and was 3·7 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·4 in Edinburgh and 15·9 in Dundee to 21·8 in Paisley and 22·6 in Greenock. The 526 deaths in these towns included 61 which were referred to diarrhœa, 12 to whooping-cough, 8 to measles, 6 to scarlet fever, 3 to "fever," 1 to diphtheria, and not one to small-pox. In all, 91 deaths resulted from these principal zymotic diseases, against 98 and 121 in the two preceding weeks. These 91 deaths were equal to an annual rate of 3·2 per 1000, which was 2·4 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had risen from 25 to 72 in the five preceding weeks, declined again to 61 last week, of which 33 occurred in Glasgow, 10 in Dundee, 8 in Paisley, and 4 in Greenock. The deaths referred to whooping-cough, which had been 10 and 18 in the two preceding weeks, declined to 12 last week, and included 6 in Glasgow. The 8 fatal cases of measles showed a further decline from the numbers recorded in recent weeks, and included 4 in Glasgow and 2 in Greenock. The deaths from scarlet fever, which had increased from 1 to 6 in the three preceding weeks, were again 6 last week, of which 2 occurred in Glasgow, 2 in Edinburgh, and 2 in Leith. The 3 fatal cases of "fever" showed a decline of 7 from the number in the preceding week; and the death from diphtheria was recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 79 and 80 in the two preceding weeks, declined to 57 last week, and were 18 below the number in the corresponding week of last year. The causes of 40, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·9 and 20·0 per 1000 in the two preceding weeks, rose again to 25·1 during the week ending July 20th. During the past three weeks of the current quarter the death-rate in the city has averaged 23·3 per 1000, the death-rate during the same period being 20·9 in London and 16·4 in Edinburgh. The 168 deaths registered in Dublin during the week under notice showed an increase of 34 upon the number in the previous week, and included 21 which were referred to the principal zymotic diseases, against numbers increasing from 9 to 16 in the three preceding weeks; of these, 16 resulted from diarrhœa, 3 from whooping-cough, 2 from small-pox, and not one either from measles, scarlet fever, diphtheria, or "fever." These 21 deaths were equal to an annual rate of 3·1 per 1000, the zymotic death-rate during the same period being 6·5 in London and 1·7 in Edinburgh. The fatal cases of diarrhœa, which had steadily increased from 3 to 10 in the four preceding weeks, further rose to 16 last week. The 3 deaths referred to whooping-cough exceeded the number recorded in any recent week, while the 2 fatal cases of small-pox corresponded with the number in the preceding week. The 168 deaths in Dublin last week included 47 of infants under one year of age, and 34 of persons aged upwards of sixty years; the deaths of infants considerably exceeded those recorded in any recent week, and the deaths of elderly persons also showed a slight increase. Eight inquest cases and 7 deaths from violence were registered; and 40, or nearly a fourth, of the deaths occurred in public institutions. The causes of 13, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL MAJOR has arrived at Singapore, and taken over Medical Charge. Surgeon-Lieutenant-Colonel Chapman, retired pay, has been appointed to Lincoln. Surgeon-Major Thiele has been granted sick leave from Malta. Surgeon-Captain Hickson has arrived in England from the Cape, and Surgeon-Captain Duggan has embarked for the West Coast of Africa. Surgeon-Captain Corkery has been transferred from Gravesend to Reading.

ARMY MEDICAL STAFF.

Surgeon-Colonel Samuel Archer is placed on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following promotions among the officers of the Indian Medical Services:—*Madras Medical Establishment:* Surgeon-Majors to be Surgeon-Lieutenant-Colonels: George Tucker Thomas, Arthur James Sturmer, and Archibald Adams, M.D. To be Surgeon-Major: Surgeon-Captain Arthur Owen Evans. *Bombay Medical Establishment:* Surgeon-Majors to be Surgeon-Lieutenant-Colonels: Arthur Henry Coles Dane, M.D.; John Philip Greany, M.D.; George Edward Elton Burroughs; and James McCloghry. Surgeon-Captains to be Surgeon-Majors: Mackintosh Alexander Thomas Collie and William Henry Quicke. Her Majesty has also approved of the retirement from the service of the undermentioned officers:—*Madras Medical Establishment:* Surgeon-Colonel A. Porter, M.D.; Brigade-Surgeon-Lieutenant-Colonel Arthur Luke Hackett; Brigade-Surgeon-Lieutenant-Colonel Patrick Richard Martin, M.D.; and Surgeon-Major Donald Elcum. *Bombay Medical Establishment:* Surgeon-Lieutenant-Colonel George Edward Elton Burroughs. Surgeon-Captain W. H. B. Robinson, 34th Bengal Infantry, is appointed to Medical Charge of the British Agent's Escort, Gilgit. Surgeon-Captain W. C. Sprague is appointed to officiate in Medical Charge, 13th Bombay Infantry, at Aden, during the absence of Surgeon-Lieutenant-Colonel S. B. Haliday, or until further orders. Surgeon-Major W. H. Neilson (Madras), on return from garrison duty, is reappointed to officiate as Agency Surgeon at Alwar until further orders. Surgeon-Lieutenant-Colonel Henry Hyde (Madras) retires from the service subject to Her Majesty's approval.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant William George Creswell, M.D., has been promoted to Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 8th Lancashire: Surgeon-Lieutenant W. McClelland, M.B., resigns his commission. *Rifle:* 2nd (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment: Henry Ashton Rudyard, Gent., to be Surgeon-Lieutenant. 1st (Brecknockshire) Volunteer Battalion the South Wales Borderers: Surgeon-Major P. E. Hill to be Surgeon-Lieutenant-Colonel. 1st Tower Hamlets: Alfred Croudson Tunstall, M.D., to be Surgeon-Lieutenant.

VOLUNTEER INFANTRY BRIGADES.

Forth Brigade: Surgeon-Lieutenant-Colonel P. H. Watson, the Queen's Rifle Volunteer Brigade Royal Scots (Lothian Regiment), to be Brigade-Surgeon-Lieutenant-Colonel. *North Midland Brigade:* Surgeon-Lieutenant-Colonel T. L. Gentles, 1st Volunteer Battalion the Derbyshire Regiment, to be Brigade-Surgeon-Lieutenant-Colonel.

PASTEUR FILTERS FOR THE ARMY OF OCCUPATION IN EGYPT AND INDIA.

About a year and a half ago, a correspondent in Egypt writes, an experiment was made of furnishing some of the English troops in Alexandria with Pasteur-Chamberland filters, and now, after much correspondence, it is confidently hoped that the War Office will allow the exclusive use of these filters in both hospitals and barracks in Cairo and Alexandria. The medical officers advise, the General approves, but the difficulty is to arouse the supine energies of the financial officials in London. At present the barracks are provided with nothing but native earthenware filters, and the patients in hospital are exposed to the dangers of old-fashioned charcoal jars. Soldiers will always continue to drink from unclean supplies while out of barracks, but at present the Government, in

Digitized by Google

deploring the existence of endemic enteric fever, has no right to cavil at the causes abroad so long as the purest available water is not supplied to the troops when they are in barracks. English soldiers in Egypt require special protection against typhoid fever partly because their racial peculiarities cause them to suffer from diseases from which the population of Egypt seems almost exempt, and partly because for some unknown reason, the deferred age of young soldiers for service in India has not yet been applied to Egypt, and, therefore, the regiments newly arriving in the country are exactly at the time of life when they are most liable to enteric fever. It is well known that the French and German armies have reported on the decrease of typhoid fever after the introduction of such filters as the Pasteur-Chamberland, and, moreover, they have been for some years adopted in the Egyptian hospitals of Cairo and Alexandria. Drunkenness is another of the blots of the English army, and it is very gratifying to know that a measure introduced a year ago has so far been a great success. A lighter and cheaper beer (5*d*. per quart instead of 7*d*.), and much more suitable to the needs of a hot climate, has been furnished by an English brewery, and, after some natural hesitation on the part of the men, it has now become very popular with all ranks. Though actually more beer is consumed in the canteens than formerly, drunkenness and the necessary punishments have considerably diminished. It is, however, open to question whether the authorities are wise in choosing the hour immediately before the midday meal as the one during which the canteen shall be thrown open. The old soldier pretends that he cannot dine until he and his friends have gulped down a gallon of beer, but with the present short service system the State should think twice before it returns to society an individual who has been encouraged to cultivate drinking habits on an empty stomach.

The *Times of India* says: "The Commissioners of Darjeeling have arranged to introduce the Pasteur system filters into their water mains, and though so many thousands and tens of thousands of these filters are in use, it is curious that the largest single installation and the first application of the system to a town supply should be carried out in a small municipality high up in the Eastern Himalayas."

THE FRENCH AND MADAGASCAR.

As might have been confidently anticipated, for it is usual in campaigns of this nature for the casualties from disease and sickness to be excessive in comparison with those received in action, the French expeditionary force in Madagascar has suffered greatly from fever. It has been determined to send a number of invalids to France *viâ* the Red Sea and Suez Canal to Marseilles instead of to the Isle de Réunion as previously proposed. The French press is much dissatisfied with this arrangement, and dwells upon the risk and discomfort which the sick and fever stricken will have to encounter at this season in the Red Sea. No doubt this is a grave consideration, but it is a choice of evils, and we are not at all sure that the French Government are not acting prudently in the course they propose to adopt. A soldier seriously affected or enervated by malarious disease does not recover and become fit for field service for a long time; he needs a complete change of climate and he longs, as a rule, to get home, and not to go to any sanatoria abroad. Of course, where a number of sick are concerned they require to be very carefully inspected before embarking on shipboard in order to guard against those being sent who are unfit to undertake a voyage to Marseilles, on the one hand, and those who do not require it for the recovery of their health, on the other. The transports and troopships for the conveyance of the invalids require to be large, roomy, and well ventilated, and every care should be taken against their being overcrowded—a matter about which the French are not by any means too careful. The organisation of the French Medical Service is very good, and it is well equipped and supplied with the necessary *matériel* for hospital and field service.

THE CHITRAL HONOURS AND REWARDS.

We confess that we are not at all surprised at the expressions of opinion which have been made in the press and military circles at the meagre rewards that have been bestowed on many of those who played a very prominent part in the brilliant siege and relief of Chitral. Colonel Kelly, for example, merited much more than he has obtained. A Companionship of the Bath is, it seems to us, an inadequate reward for the splendid services he performed. It should have been a Knight Commandership, and there are several precedents for the bestowal of this titular distinction upon officers who were not already in possession of the Companionship. Captain Townshend's services in military command of the garrison of Chitral also cannot be said to have been generously rewarded, and we think the same may be said of Surgeon-Major Sir George Robertson, considering the nature of the services he rendered and his grave responsibilities. We are glad to learn from an announcement in the *Pioneer Mail* of the 26th ultimo, that a long list is shortly to be published of native officers and sepoys on whom the order of merit has been conferred for the defence and relief of Chitral, and that the Government of India have been wisely generous in the bestowal of this reward which carries enhanced pay with it. All who took part in this campaign, whether Europeans or natives, did well, and deserve well of the country they served.

THE REBELLION IN CUBA.

In addition to the hard fighting which the Spanish expeditionary forces have had in Cuba, which rendered the despatch of strong reinforcements essentially necessary, the Spanish soldiers have recently suffered much from an outbreak of yellow fever. According to the official telegrams 2900 had been attacked with that disease, with 104 deaths, the remainder recovering. From these numbers it would seem that a great many of the cases were either of a mild character or were not really yellow fever, but other and less fatal forms of fever. Marshal Martinez Campos' force on its way to Bayamo was apparently surprised and attacked by a very large body of insurgents. The Spanish troops are stated to have fought with great valour and to have effected their retreat under cover of several charges made by a body of men under the command of General Santo Cildes, who was killed in one of these charges. Marshal Campos, who has the reputation of being a very able and experienced commander, is stated to have conducted a brilliant retreat with great skill and intrepidity. It seems clear that the rebellion in Cuba is a serious business, which will cost the Spanish Government a good deal of expenditure in men and money to effectually overcome.

CALCUTTA.

The sanitary state of Calcutta does not seem to be at all satisfactory, if we may judge from a recent report by the health officer of that city. The *Times of India* of the 28th ult., in calling attention to the subject, says that the condition of Bombay is a matter of only too frequent comment; but Bombay would seem to be Hygeia itself compared with Calcutta. One of the great evils of the latter city is overcrowding and want of attention to the formation of proper streets and buildings. This is said to be becoming worse every year. The difficulty of cleansing the city and of making any sanitary progress is an increasing one under such circumstances. Dr. Simpson has been representing these and other matters for several years, but it does not appear that he has been successful in getting the municipal authorities to take any practical action. The state of the public health of Calcutta has not been such of late years as to justify the city authorities in their course of inaction—quite the contrary. One of these days there will be some outbreak of epidemic disease on a large scale, and they will then be compelled to do something. What is the good of having an experienced and energetic health officer and of paying him a salary for giving sound advice if there is no intention of following it?

THE MILITIA MEDICAL STAFF CORPS.

The Militia Medical Staff Corps is now under training on the Redan Hill, Aldershot, under the command of Surgeon-Major Collingridge. The three companies—Hampshire, Middlesex, and Surrey—have their full establishment of officers. Two new companies are to be shortly formed which will require four officers. As the pay and allowances amount to about 22*s*. per diem there are likely to be numerous candidates for the commission. Application should therefore be made at once to the commanding officer.

The Maidstone Company of the Volunteer Medical Staff Corps will arrive at Netley on Saturday, Aug. 3rd, for the usual training.

DISTRICT PRINCIPAL MEDICAL OFFICERS IN INDIA.

It has been ruled that a District Principal Medical Officer will move to the hills when the general officer commanding

Digitized by Google

does so, provided that neither the State nor the clerks are put to any extra expense thereby.

NAVAL MEDICAL DEPARTMENT.

An examination of candidates for ten commissions in the Medical Department of the Royal Navy will be held in the Examination Hall, Victoria Embankment, on Monday, Nov. 4th, 1895, and following days.

The extra pension of £100 per annum due to the Bombay Establishment of the Indian Medical Service for 1895–96 has been allotted to Brigade-Surgeon-Lieutenant-Colonel Colin Wm. MacRury, on his retirement from the service.

Correspondence.

"Audi alteram partem."

"THE CARDIO-VASCULAR CHANGES OF RENAL DISEASE."

To the Editors of THE LANCET.

SIRS,—Before proceeding to comment upon some parts of Dr. Dickinson's interesting and instructive lecture on the above subject I beg to thank him for the generous appreciation of my own work, which he has expressed in the following sentence: "It has been well known since the observation of Sir G. Johnson—which represents a great truth, however it is to be interpreted—that with the chronic granular kidney the arterioles, even to the smallest, become hypertrophied."

I gratefully acknowledge the fact that Dr. Dickinson was one of the first amongst eminent pathologists to publicly express his opinion that what I described as hypertrophy of the walls of the arterioles was really such. That the thickening of the walls is not, as various writers have suggested, a result of "lardaceous degeneration," of a so-called "hyalin-fibroid change," or of any form of "arteritis." There being now a general agreement as to the anatomical facts the question of their interpretation alone remains for discussion. In giving a brief history of former controversies Dr. Dickinson makes the following statement: "Johnson, in upholding the muscular thickening, denied the fibrous, the appearance of which he holds to be delusive and the result of reagents." Now I admit that in my early publications on this subject I directed attention mainly to hypertrophy of the muscular layer of the arterioles; but for a long time past I have recognised the fact that in arterioles thickened by hypertrophy there is an over-growth of all the normal tissues. So in the hypertrophied heart there is an increase not only of muscular fibre, but of all the tissues of which the heart's walls are composed. If Dr. Dickinson will do me the favour to refer to my "Medical Lectures and Essays," published in 1887, he will find that at page 699 I have borrowed his own illustrations to show in an artery from the pia mater in a case of granular kidney "the muscular coat and the adventitia hypertrophied." Then it is not quite correct to say that I ever attributed the *fibrous* appearance to the result of reagents. My contention was that the *hyaline* appearance of the tunica adventitia in the arteries of the pia mater is the result of the glycerine in which they were preserved; and that this is the true explanation of the appearance was proved by the fact that after the reading and discussion of the paper by Sir Wm. Gull and Dr. Sutton at the Royal Medical and Chirurgical Society they both recognised in a specimen which I showed them the hyaline condition which they had described as pathological, the specimen in question being arterioles from the pia mater of a sheep, and the adventitia having been rendered hyaline by acidulated glycerine.

With regard to the seat and nature of the obstruction in the terminal vessels which gives rise to the cardiac hypertrophy, Dr. Dickinson thinks it unlikely that the heart and the arterioles should antagonise each other, yet surely the doctrine of all modern physiologists is that while the heart, assisted by the large elastic arteries, propels the blood onwards, the muscular walled arterioles, by their contraction and relaxation, regulate the blood supply to the capillaries. This apparent antagonism results in harmonious coöperation; so, to compare very great forces with very small ones, the position and movements of the planets are regulated by the marvellous coöperation and equipoise of the opposing centripetal and centrifugal forces. Dr. Dickinson is still inclined to the opinion that the capillaries are, in part at least, the seat and cause of the impeded circulation in renal disease, and he considers that this view receives support from the fact that not only are the walls of the arterioles thickened, but also those of the large arteries, from the aorta downwards. He has carefully measured the actual thickness of the walls and the circumference of numerous arteries from the subjects of granular kidney, comparing them with the corresponding normal arteries, and has tabulated the results. The amount of thickening, though constant, is very small as compared with the very much greater thickness of the arterioles. For instance, the thickness of the normal renal artery, as compared with the artery of a granular kidney, is in the proportion of eighteen to twenty-five. Now, compare this with the arterioles of a granular kidney, which may commonly be seen to be three or four times thicker than the corresponding normal vessels. Dr. Dickinson admits that if the arterial hypertrophy were limited to the smaller vessels the stopcock action might be the cause of the hypertrophy, and surely, by parity of reasoning, the enormous excess of hypertrophy of the arterioles affords conclusive evidence of the long-continued over action of these vital stopcocks. At the present day it will scarcely be contended that the great hypertrophy of the arterial walls is caused by an imaginary impediment in the thin-walled capillaries which they supply. That, indeed, was the explanation which I suggested forty-five years ago, in a paper which was published in the thirty-third volume of the Royal Medical and Chirurgical Society's Transactions. The excuse for my erroneous physiology is that the paper in question was written about two years before the publication of the earliest of M. Claude Bernard's epoch-making experiments on the vaso-motor nervous system.

The thickening and dilatation of the larger arteries which have long been recognised as clinical facts, and which have now for the first time been measured, are just such conditions as might have been expected to result from the strain to which they are subjected between the hypertrophied left ventricle behind and the hypertrophied arterioles in front. If the walls of arteries which are exposed to such high pressure did not become strengthened by hypertrophy, the inevitable result would be a much more frequent occurrence of disastrous dilatation and rupture than is actually found to happen.

The theory of capillary obstruction, apart from inflammation, which is not here in question, was plausible enough in the days of Dr. Alison and Dr. John Reid, but since the discovery of the structure and function of the arterioles and of the vaso-motor nervous system the hypothesis in question, unsupported as it is by facts, has been shown to be superfluous and untenable. The function of the arterioles and of the capillaries respectively is as different as is the structure of their walls. This is stated with characteristic clearness in the following extract from Professor Huxley's "Elementary Physiology": "While the small arteries lose the function which the capillaries possess of directly irrigating the tissues by transudation, they gain that of regulating the supply of fluid to the irrigators or capillaries themselves. The constriction or dilatation of the arteries which supply a set of capillaries comes to the same result as lowering or raising the sluice-gates of a system of irrigation canals." It will be seen that Professor Huxley's comparison with the action of "sluice-gates" and mine with that of "stopcocks" express an identity of view as to the regulating function of the arterioles, this view of their function being, as I believe, that of all modern physiologists.—I am, Sirs, yours faithfully,

Savile-row, July 22nd, 1895. GEORGE JOHNSON.

"SPECIALISM IN MEDICINE."

To the Editors of THE LANCET.

SIRS,—To be able to claim membership of the medical profession is to me the highest honour. In my estimation the profession stands second to none, for I know that beyond any other it is composed of men leading lives of true self-sacrifice and devotion to duty. It is with these feelings and with a full sense of the responsibility of taking such a position that I venture confidently to impugn some of the main statements in the leading article in your issue of July 20th. Dealing with the question of the abuse of specialism, you inquire whether quackery occurs among any section of specialists. You ask, "Are needless operations performed

Digitized by Google

for fees? Are methods of treatment urged upon patients for commercial rather than pathological reasons?" Your answer is that "practically neither abuse exists."

Not a month, hardly a week, passes that I do not learn the authentic details of cases of quackery by a class of practitioners, mostly specialists; and I venture to affirm without fear of contradiction that there is not to be found a single consultant, specialist, or general practitioner of any experience who cannot from personal knowledge vouch for the fact that there exists in London a considerable number of men, mostly specialists, who show by their methods that their object is not to obtain fair remuneration for honest work, that their aim before all things is not to do the best for the patient, but that their paramount consideration is the making of money, regardless of the injury inflicted upon the victims who place themselves with confidence in their hands. That quackery outside the profession—practice by unqualified pretenders—does no harm from any point of view to the legitimate practitioner is, I believe, capable of proof. It is quackery within which does harm. Of those who fall into the hands of qualified quacks a large number never recognise that they have been victimised, but many do; and these and their friends are too often led to look with suspicion on the whole body of medical men, if they do not regard them as, without exception, on a level with the individuals by whom they have been misused, and whom they had been led to believe were eminent representatives of the profession.

I am, Sirs, your obedient servant,

Cavendish-square, July 20th, 1895. HENRY SEWILL.

THE PROFESSION AND MEDICAL AID SOCIETIES.

To the Editors of THE LANCET.

SIRS,—We are directed to inform you that a meeting of the medical profession in Eastbourne, called by the invitation of the local medical society, has been recently held for the purpose of considering proposals for the formation of a Provident Medical Association, in order to combat the growing evil of commercial "medical aid" societies in this town. At the meeting it was resolved that an association should be started upon the following lines: (1) All duly qualified resident medical men, not practising as homœopaths, to be eligible for the acting staff, subject to the approval of the committee; (2) the committee to be exclusively a professional one, consisting of the staff and a certain number of members appointed by the Eastbourne Medical Society; (3) a wage-limit or other check to abuse to be adopted; and (4) the profits, after payment of working expenses, to be divided amongst the acting staff proportionately to the number of members upon their respective lists.

The following resolutions were also adopted:—1. That every medical man in Eastbourne be invited to sign a statement agreeing neither to accept any appointment himself in any "medical aid" or similar society, nor to have any professional intercourse whatsoever with any medical practitioner holding any appointment in, or associating himself in any way with, any of the so-called "medical aid societies," or with any similar company so long as the methods adopted by these societies include (*a*) canvassing for members in the interest of individual practitioners; (*b*) the virtual "sweating" of their medical officers by the inadequate remuneration for the work done. 2. That, considering the necessity for permanently maintaining united action on the part of the profession towards these medical aid societies, this meeting approves the plan of requesting the committee of the Eastbourne Provident Medical Association to depute one of its members to call upon every new medical practitioner settling in Eastbourne, with the object of warning him against the methods of the medical aid societies and of courteously inviting his signature to the above agreement. 3. That the British Medical Association be requested to approach the Deans of the various medical schools in the United Kingdom, and urge them to point out to their senior and recently qualified students—(*a*) the very objectionable character of these medical aid societies; (*b*) that the Royal College of Surgeons of England and the Royal College of Physicians of Ireland have both expressed in clear terms their disapproval of their diplomates associating themselves with these societies; (*c*) that the committee appointed by the General Medical Council to inquire into the working of these societies in relation to the medical profession unanimously condemned their methods; and (*d*) that by accepting appointments in these societies medical practitioners will cut themselves off from their professional brethren.

It was further agreed to send copies of these resolutions to the medical journals in the hope of warning inexperienced junior practitioners who might otherwise accept posts under medical aid societies in Eastbourne. The following practitioners signed the agreement embodied in the first resolution:—

Adams, James,	Holst, Otto,
Barnes, A. R.,	Jackson, G. H.,
Browne, D. Matthews,	Jones, J. Talfourd,
Cameron, Chas. H. H.,	MacQueen, Thos.,
Colgate, Henry,	Marsdin, Fredk.,
Daly, Wm. J.,	Pollock, William,

Hon. Sec., *pro tem.*, Eastbourne Provident Medical Association.

Eastbourne, July 22nd, 1895.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE PORTRAIT OF SIR JOSEPH LISTER.

To the Editors of THE LANCET.

SIRS,—The Fellows and Members of the Royal College of Surgeons of England have just received a circular headed "Sir Joseph Lister (College of Surgeons) Portrait Fund," inviting subscriptions, and stating that "Mr. W. W. Ouless, R.A., has, at the request of the committee, undertaken to paint the portrait." This committee appears to be practically self-elected, and I would ask if such a committee, however eminent individually, should have proceeded so far without first having a mandate from the general body of subscribers. Everyone must feel that the artist does not live to whom it would not be an honour to paint the portrait of Lister, which is to hang beside Reynolds's John Hunter, and I would suggest that this honour ought to be given to a painter carefully selected after due inquiry by a committee chosen at a meeting of the general body of subscribers, and conferring with the authorities of the College, whose right and duty it is to have a voice in the matter.

I remain, Sirs, your obedient servant,

Grosvenor-street, W., July 23rd, 1895. C. B. KEETLEY.

"THE DUTIES OF MEDICAL SOCIETIES."

To the Editors of THE LANCET.

SIRS,—My attention has been called to an article in THE LANCET of July 20th commenting, under the above title, upon a case of prolapse of the uterus which I treated by extirpation. Perhaps you will allow me to give a few details of the case. The patient was a single woman thirty years of age. She gave birth to a child five years before coming under my care. The confinement was a troublesome one and was followed by protrusion of the uterus. When I first saw her she was in a deplorable condition. The uterus, much enlarged, was lying between her thighs, and there was complete and extensive prolapse of both bladder and rectum. The perinæum was destroyed and the vulval orifice in consequence very large. A fair trial was made with pessaries without the slightest benefit. The tissues were too much thinned and stretched to make perineorrhaphy at all a hopeful procedure, and I came to the conclusion that extirpation was the only operation likely to be followed by success. The patient soon got well and the result has given her the greatest satisfaction and comfort, and she is now able to earn her own living. I trust the exceptional character of the case may justify the treatment adopted.

I am, Sirs, yours faithfully,

Weymouth, July 23rd, 1895. MACPHERSON LAWRIE.

INFANTRY SWORD EXERCISE AND THE RECENT HANDBOOK FROM THE WAR OFFICE.

To the Editors of THE LANCET.

SIRS,—This handbook of instructions in the use of the sword has just been issued by the War Office. As the document is official and imposes on the British soldier certain methods of attack and defence, it is not out of place to inquire into the soundness of the principles involved in the teaching, both from physiological and practical points of view. The system here ordered for adoption is that of the Italian school, as modified by Cavaliere Masiello of Florence. The Italian system has been weighed in the balances of experience and found wanting; it is now almost universally superseded by the French school. We fail, therefore, to understand why our authorities should have revived a faulty and more or less exploded method. The position of the body and limbs now recommended (we should say ordered) are essentially faulty, entailing, as they do, unnecessary outlay of muscular power, and leading by their unnatural conditions to rapid nerve-exhaustion. The "guard" itself, with the feet widely separated, "with both shoulders and sword parallel to the directing line," and the attacking arm prone and fully extended, involves an attitude quickly inducing fatigue and unsteadiness, and this without any adequate compensation. The brachial and deltoid muscles get easily tired, the more so as the elbow-joint is fixed as completely as if it were ankylosed, and the suggestion in the handbook that it should "serve as a pivot" is an anatomical impossibility. From such a position it is evident that rapid recovery after the lunge is most difficult, and thus the fencer is exposed to great risk if engaged with an active opponent skilled in the French method. We write as representing the feelings and judgment of many members of the medical profession who are interested in fencing as an amusement and exercise, as well as a discipline for the officers and soldiers of the British Army. That a method so faulty and unsound should be now presented to the British soldier for his instruction and guidance appears to us a measure distinctly retrograde and dangerous.—We are, Sirs, yours faithfully,

I. D. CHEPMELL, M.D.,
G. H. SAVAGE, M.D., F.R.C.P.

July 23rd, 1895.

VOLUNTEER MEDICAL STAFF.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to say that through the courtesy of the Council of the British Institute of Public Health, arrangements have been made this year, as in previous years, for the officers of the Volunteer Medical Staff to dine together on the occasion of their annual banquet, on Wednesday, July 31st, at 7 P.M., in the King's Hall of the Holborn Restaurant. A large number of distinguished officers and guests have been invited by the Council, and it is hoped H.R.H. the Duke of Cambridge will also be present; and as this is probably the last public occasion at which His Royal Highness will appear before his retiral, it is believed that a large number of Volunteer medical officers would like to attend. Tickets may be obtained of the Secretary, Mr. C. A. James, at the address given below.

I am, Sirs, yours faithfully,
W. GUYER HUNTER, K.C.M.G., M.D., &c.,
Chairman of Council of the Volunteer Medical Association.
20, Hanover-square, W., July 22nd, 1895.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Poor-law Relief in Manchester.

MR. GUILMETTE, the superintendent of the relief department of the board of guardians, has issued his annual report for the year ending March 23rd last. In some respects it is encouraging, especially if we bear in mind the long-continued depression of trade from which this district has suffered. During the half-year ending September, 1870, the total number of in-door poor relieved was 7388, and in the corresponding half-year of 1894 they numbered 7437, an increase of 85 persons, or 1 per cent. During the same half-years respectively the total of the out-door poor of the township numbered 13,992 and 2474, a decrease of 82 per cent. On Jan. 1st, 1871, 60 per 1000 of the inhabitants of the township were in receipt of relief, while on Jan. 1st, 1895, the proportion had fallen to 31 per 1000, a decrease of nearly 50 per cent. On Jan. 1st last the number of in-door poor was 3667, equalling the population of a large village or small town, and the duty devolving on the guardians for the efficient oversight of this community, its provisioning, the treatment of its sick, the education and starting in life of its young, and the employment in suitable occupations of its adults, must be considered a work of some magnitude and importance. Of this large number there were not 50 men at the very outside who could be called "able-bodied" "in the sense of being possessed of that muscularity which would fit them to successfully compete for work with the average out-door labourer," and many even of these, from having led roving, unsettled lives or from drinking habits, "would be unlikely to find a regular place of work congenial." The term "able-bodied" is one of wide application and includes many cases which the non-official mind would certainly place in another category. "The 'able-bodied' also include 928 persons suffering from temporary sickness, and who are laid up in bed under the care of the medical officers. They further include persons who, being neither properly 'sick' nor 'infirm,' and able to do a little light jobbing about, are nevertheless in reality shut out from engaging in most of the active occupations of life—those who suffer from occasional fits, are partly blind, minus an arm or leg, of weak intellect, or are the victims of congenital or acquired physical or mental defects." There are also in the workhouse 269 lunatics, imbeciles, and idiots (exclusive of 325 in asylums), and 1142 classified as "infirm"—these include the sick and bedridden, the paralysed, the very feeble and helpless, &c. There are also 740 children under the care of the guardians, of whom the majority are being trained and educated at the Swinton Separate Schools. Last year there was an enormous influx of vagrants, no fewer than 52,319 having been admitted into the tramp wards. These numbers so tax the accommodation that the labour test cannot be strictly applied, nor the usual period of detention enforced. This soon becomes known, "with the result that whilst the numbers steadily go up the power to apply deterrent treatment steadily goes down." The report goes on to show how difficult it is to give help to the deserving or destitute without some accompanying evil, for it says: "There is little doubt that a number of those who used the tramp wards last winter were attracted to the district by the advertisement of free meals and the extensive distribution of private charity during the great frost." The increase in the number of tramps is a serious matter. Five years ago there were only 14,182. They come not only from the lower classes but from the social failures of those above them, who from faults and failings of character and conduct have drifted down among the homeless and destitute. Mr. Guilmette sees great difficulties in any attempt at classifying the deserving and the worthless. "There are great dangers of errors of discrimination; there is the enmity, falsehood, or ignorance of one informant and the favourable prejudice and partiality of another; the absence of any independent testimony in many cases, the obvious contradiction which a man's appearance and demeanour not infrequently give to his own account of himself and that of his friends,—all these present almost insurmountable obstacles in the way of carrying out a thorough system of classification of character amongst the aged poor in such a township as that of Manchester."

Salford Sewage.

Salford has had much trouble over her sewage, and seldom is a good word said for her, so it is not to be wondered at that various comments have been made as to her policy of buying a steamer in order to carry the sewage sludge out to sea. Theoretically it should go back to the land, but it is a costly matter and by no means easy to get it there. The one good deed she does ought to be mentioned. The steamer takes out 600 tons of liquid sewage three or four times a week and discharges this into the sea, to the bewilderment and injury no doubt of the fish that happen to be caught by this deluge of filth. On the return trip, however, the ballast-tanks are filled with sea water, which is discharged into the canal at Modewheel. Three or four hundred tons of sea water three or four times a week will not make much change in the condition of the

Digitized by Google

canal, but every little helps, and it is said to be "a refreshing sight to see the stream of clear sea water pouring into the murky canal from the sides of the steamer." The *Manchester City News* seems to think that the Local Government Board should not insist on filtration being applied to the Manchester and Salford sewage, "seeing that the effluent is turned into a navigable canal," and that it should only require it to be innocuous. It says that the cost of treatment will be trebled by the filtration process, and asks whether a local body should be compelled to produce an effluent many degrees purer than the stream into which it is turned. If this principle were acted on there would be little hope for the purification of our rivers. An experiment in filtration is being made at Salford on a small scale by two methods. One is the Riddel process, by which the effluent, first produced by precipitation, is forced by steam and hydraulic power through beds of sand some 3 ft. deep arranged at the bottom of an iron boiler, which has the appearance of an ordinary steam boiler. To treat the 10,000,000 gallons of Salford sewage twelve boilers 30 ft. long and 8ft. deep would be required, and "to cope with the additional volume brought down by a heavy rain would require probably as many more always to be in readiness." The result is said to be excellent, but the question of cost is the difficulty. The other process, devised by Mr. Corbett, the borough engineer, consists of open-air beds or tanks with a layer of sand and gravel, through which the effluent slowly filters. The effluent is "surprisingly clear"; but here again the serious matter is the cost. It would require many acres to treat the ordinary 10,000,000 gallons a day, and as many more acres to deal with a flood. It is said that a very ordinary downpour of rain will raise the quantity to 14,000,000 or 16,000,000 gallons. In the case of Manchester these figures would have to be trebled or quadrupled if she adopted either of these processes.

Mr. Maclaren's Batting Feat.

For the last week or two the stress and turmoil of electioneering struggles have occupied the attention of the Manchester people, to the exclusion of pretty nearly everything else; but Mr. A. C. Maclaren's marvellous innings against Somersetshire has aroused the enthusiasm of the many thousands of our local lovers of cricket. His 424 runs, made in 470 minutes, won the match with 79 to spare, so that the 377 contributed by the other members of the Lancashire team—making the total up to 801—were not required. The quickness and correctness of eye, the instantaneous response of the muscles to the constantly recurring messages flashed to the brain, and the endless repetition of the run "between the wickets," tell a story of muscular and nervous endurance of much physiological interest. Mr. Maclaren was captain of the Harrow team in 1890, and though only twenty-three has captained the Lancashire eleven for the last two years. His scholastic duties—he is now qualifying for a mastership at Harrow—have prevented him playing for his county since the first few matches, but as he will be free to the end of the season he may now, perhaps, play more frequently. I may be permitted to add that he is a nephew by marriage of our distinguished *confrère*, Dr. Leech.

Adult Deaf and Dumb Institute.

The claims of the above charity are not often brought before the public, and it has depended on a small band of yearly subscribers. And yet it does a large amount of good work, for there are in Manchester and the neighbourhood nearly 1000 deaf mutes, to whom its numerous benefits are always open. It occurred to the Lady Mayoress, who takes a warm interest in its welfare, that its funds might be increased by the pleasurable means of a garden party at the Botanical Gardens. The idea culminated in most successful gatherings on Friday and Saturday of the week before last. Large numbers were present on both days, and the pecuniary benefit to the charity will no doubt be considerable, though the actual figures cannot as yet be given. On the Saturday afternoon a large party of the deaf and dumb were entertained at tea by the Lady Mayoress, who afterwards spoke to them, the secretary, Dr. Buxton, acting as interpreter. "The quick apprehension of everything, expressed by a demonstration of smiles and quaint gestures, was extremely touching." It was computed that nearly 12,000 people were present.

Home for Crippled Children.

This institution is a branch of the Boys and Girls Refuges, and, as its name implies, makes those among the waifs who start life under physical difficulties its special care. At present there are between thirty and forty crippled or incurable boys and girls in the home at Cheetham-hill. Many of them are able to pass their time in making articles for the annual sale of work which takes place on their *fête* day, which was held the other week. The Lady Mayoress, who constantly manifests her sympathy with philanthropic work, opened the sale, and there was a large attendance.

High Schools for Girls.

Professor Clifford Allbutt has just paid Manchester a visit, and on Friday last gave an interesting and instructive address in the Free Trade Hall to the pupils of the High Schools for Girls at the distribution of prizes and certificates gained during the year.

July 23rd, 1895.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Retirement of Mr. Macdonald Brown from Surgeons' Hall.

IT will be a surprise to many of Mr. Macdonald Brown's old pupils to learn that he has retired from his position as Lecturer on Anatomy in the Edinburgh School of Medicine, and proposes to devote himself to practice. This change has come as a surprise to those connected with the extra-mural school, as he has been a successful lecturer for a number of years. He is succeeded at Surgeons' Hall by Mr. J. Ryland Whitaker, M.B.Lond., F.R.C.P. Edin., who goes from Minto House, where he had succeeded Dr. Symington. The probabilities are that the teaching of anatomy to men in the extra-mural school will now be confined to Surgeons' Hall and the New School.

The Edinburgh Dental School.

The presentation of prizes in connexion with this school took place last week. The Dean referred to the continued success of the school, and stated that there were thirty-seven students on the working roll. Professor Chiene addressed the students on the career of Robert Nasmyth, the father of Scottish dentistry, because he had made anatomy the basis of his work, and, further, because he was the man who brought to Edinburgh the great John Goodsir.

Close of the Summer Session in Edinburgh.

The summer session, both in the University and extra-mural schools of Edinburgh, was brought to a close last week without any noteworthy incident. The first professional examination at the University is at present going on, and no fewer than thirty female students, it is understood, have entered for it. Most of these have either already qualified in medicine or are senior students of medicine who have had the courage to go back over their old work, prompted by the laudable ambition of obtaining the University degree. One female student has presented herself for the second professional examination, having passed the first in April.

Health of Edinburgh.

During the month of June the total number of deaths were 354, giving a death-rate of 15·52 per 1000, compared with 14·36 for June last year. The average death-rate for the last five years was 16·06.

Health of Aberdeen.

During the week ending July 20th 55 cases of zymotic disease were reported to the sanitary office. This is an increase of 16 on the preceding week. Of whooping-cough there were 41 cases, measles 2, erysipelas 3, and choleraic diarrhœa 1.

Extension of Buildings, University of Aberdeen.

An official statement laid before the executive committee shows that the subscriptions towards this scheme up to April 10th—including £40,000 of grant from Government—amounted to £92,398 odd. The liabilities amounted to £108,124, the cost of sites—namely, £50,011—having unavoidably been heavy. The fine stained glass windows in the Graduation Hall and the clock and finials are to be provided by Mr. Charles Mitchell, LL.D., of Newcastle-upon-Tyne, while the estimated cost of the works already undertaken, and for which the executive committee is responsible, is £78,261. The committee has resolved to appeal to the new Government for a further grant of £20,000, and also to private friends for further contributions, so as to allow the modified scheme to be completed. An effort is to be made to have the front buildings finished with fine-axed stones, which would add greatly to the effect, as the white granite which

Digitized by Google

is being used looks beautiful when so treated. The gable towards Broad-street of the north wing, and that towards East North-street of the Graduation Hall, will contain large windows and be among the most striking architectural features of the new buildings. The Mitchell Tower, from its great height and its graceful outlines, is regarded with admiration by all visitors from a distance, and it surpasses all other granite structures even in the "Granite City" itself.

The Member of Parliament for West Aberdeenshire.

One of the few members of the medical profession returned to the new Parliament is Dr. Robert Farquharson of Finzean, Aberdeenshire, who has on this occasion increased his majority to 220. Dr. Farquharson has represented West Aberdeenshire since April, 1880. Had it not been for his attitude on the Church of Scotland question, and his recent action in connexion with the proposal to raise the age limit of boy labour for night work in paper mills, it is believed Dr. Farquharson's majority would have been considerably higher.

July 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Case of Successful Innominate Ligature.

MR. COPPINGER'S patient, whose innominate artery was successfully ligatured in January, 1893,[1] for the cure of subclavian aneurysm, is now being exhibited in London. The operation was performed at the Mater Misericordiæ Hospital. The man was shown six weeks afterwards at a meeting of the Royal Academy of Medicine in Dublin as a case of successful ligature of the innominate artery, and six months later at Newcastle-on-Tyne as an instance of cure of subclavian aneurysm by simultaneous ligature of the innominate and common carotid arteries. The patient, a man aged fifty-nine, is now (two years and a half after the operation) in good health, and is the only living example as yet exhibited in Europe of cure of subclavian aneurysm by innominate ligature.

Mater Misericordiæ Hospital.

A woman aged twenty-five was recently admitted to this hospital complaining of an abdominal tumour about the size of an infant's head, hard and freely movable. It had existed for two years, and there was no history that the patient had ever suffered from intestinal obstruction. On opening the abdomen Mr. More Madden discovered two enormous enteroliths occupying the cæcum and commencement of the ascending colon. They were successfully removed by incision and the formation of an intestinal fistula.

City of Dublin Hospital: Sessional Examinations.

The gold medal presented by Mr. Wheeler for the best answering in medicine has been won by Mr. William Henry Croly.

The Recent Inquiry on the Belfast Workhouse.

At a meeting of the Belfast Board of Guardians, held on July 16th, a letter was read from the Local Government Board in reference to the inquiry held by their inspector, Mr. Agnew, as to the death of a man on April 25th in the lunatic department of the workhouse. After giving a *résumé* of the evidence[2] the Local Government Board say they are of opinion that the case was one for treatment in the medical wards of the infirmary, as the organic diseases were of a more urgent nature than any epileptic affection, and this is proved by the fact that the patient died from congestion of the lungs three days after admission without any epileptic fit. The Board do not think that in the face of the protest made by the wife of the deceased man the resident medical officers were justified in sending the patient to the epileptic ward of the lunatic department without a previous consultation with the visiting medical staff, and the board are of opinion that in all doubtful cases of mental disease there should be a consultation with the visiting medical officers. The case evidently presented difficulties of diagnosis which could only have been elucidated by careful and detailed examination, and it was due to the patient that such an examination should have been made before sending him to the lunatic department. The board having been informed by their inspector that the epileptic ward is in the lunatic department of the workhouse, and that epileptics, whether sane or insane, occupy the same ward, and that they have the same recreation grounds as the lunatics and idiots, think such an arrangement most objectionable and advise its being discontinued, and that provision should be made in the infirmary for epileptic patients. Further, they recommend that provision should be made for the examination of all patients on admission by setting apart a room for the purpose. The board also think it would be desirable that where a patient is admitted on a medical certificate the resident and visiting medical officers should be handed the certificate for their information and consideration. The guardians appointed a small committee to consider this report.

The Pasteur Institute in Paris.

It does seem a most extraordinary circumstance that no attempt is being made to deal in this country with the treatment of hydrophobia from a preventive point of view. The muzzling of dogs is not by any means enforced, and people bitten by mad dogs are obliged to go to Paris to be treated. At the last meeting of the Belfast Board of Guardians (and similar cases are being constantly reported all over Ireland) the father of a boy aged seven years, who had been bitten by a dog which was said to be mad, was granted a sum of £25 to enable him to take the lad to the Pasteur Institute in Paris. The whole question of the prevention and the treatment of hydrophobia is most discreditable to medical science in the United Kingdom.

Ballysillan Water-Supply.

A deputation from this district having appeared before the Belfast board of guardians and stated that their water-supply was very bad, being drawn from a source out of which cattle and horses drank, in which dogs swam, and children bathed, asked the assistance of the board in helping them to get pure water. While the matter was referred to a committee to consider and report at a later date, it was pointed out that a new special scheme would be costly owing to litigation, it would involve great taxation, and it might not give a continuous supply. The feeling of the board was apparently that a solution of the question would be best found in the proposed extension of the borough of Belfast so as to take in the Ballysillan district, when the residents would get the water supplied by the Water Commissioners, whose new Monson scheme, when completed, would give a never-failing supply.

Curious Nuisance at Bangor, co. Down.

At a special meeting of the Bangor Town Commissioners a deputation appeared and presented a memorial on behalf of residents praying the Commissioners to exercise the powers vested in them under the Public Health Act, and have two sets of hobby horses at present located on the Shore-road removed, as, being contiguous to private residences, they, by the noises caused and the heterogeneous crowds congregated, constituted a nuisance. Dr. Bolton, J.P., as a medical practitioner and as a medical officer of health for the district, made an important statement to the effect that while he thought that in themselves the hobby horses afforded a pleasant, exhilarating, and unobjectionable form of exercise and recreation, he gave it as his opinion that on the present locations the two systems of hobby horses were objectionable and positive nuisances because of their close proximity to dwelling-houses. To people with irritable nerves or shattered nervous systems (and people in such conditions often came to Bangor as a health resort), or to children threatened with some brain disease, or to older people attacked by some feverish illness accompanied with racking headache—to all these the near sounds arising from the steam bands, with the noise of the crowds around, Dr. Bolton thought were injurious and even dangerous. After a prolonged and stormy discussion it was decided by the casting vote of the chairman that the Hon. Somerset Ward be at once approached, and that strong representation be made for the removal of the hobby horses.

Death of Mr. Robert F. Sinclair, M.B., C.M. Edin.

Intelligence has just reached Belfast of the death from pleurisy, after four days' illness, at Brewarrina, New South Wales, on June 2nd, of Dr. R. F. Sinclair. Dr. Sinclair graduated in Edinburgh University in 1881 and for some time practised in Belfast, where he was greatly respected by his medical brethren and by his patients. About six years ago

[1] See Transactions of the Royal Academy of Medicine in Ireland, 1893.

[2] See THE LANCET, June 29th, 1895.

Digitized by Google

he left Belfast to join other members of his family who had gone to New South Wales, and there he has since practised. Dr. Sinclair's early death is very much regretted by a numerous circle of sincere friends in Belfast.

High Death-rate in Belfast.

At a meeting of the Public Health Committee, held on July 18th, the medical superintendent officer of health (Dr. Whitaker) reported an unusually high death rate—30·7 per 1000, as compared with 17·4 in the corresponding week of 1894. The infant mortality under one year was great, and there were thirty-two deaths from diarrhœa, whilst in the other fifteen urban districts of Ireland the number registered as having occurred from this cause was fifteen.

Resignation of Dr. McNeary of Garvagh.

I am sorry to say that Dr. McNeary has, owing to partial paralysis, found it necessary to resign his appointment as medical officer of the Garvagh (county Derry) dispensary district, a post which he has held for a lengthened period. Indeed, he has been in the service of the Coleraine guardians since he was appointed medical officer of Articlare in 1852. The Garvagh dispensary committee, at their meeting on July 20th, expressed the deepest sympathy with Dr. McNeary in his illness, and recommended the guardians to grant him ample superannuation. This will be settled on Aug. 24th. On Aug. 16th a meeting will be held to appoint his successor.

Sudden Death of one of the Medical Men Imported by the Cork Clubs.

Dr. Joseph A. O'Sullivan died very suddenly last Thursday evening. He was out attending to his duties the previous day, and, as far as the outside public have learned, heart disease, induced by rheumatism, was the immediate cause of death. Last winter he could have been seen in various parts of the city walking in inclement weather, paying visits to his club patients, and no doubt the fatigue he then endured and the wettings to which he was subjected seriously aggravated the rheumatism from which he had previously suffered. He was educated at the Cork Queen's College, being the only one of the four imported medical men who was a native of the city, and was a favourite with his fellow students. He developed a taste for ophthalmic surgery and became a pupil at St. Mark's Hospital, Dublin. He graduated at the Royal University, and afterwards proceeded to London, where he was about to buy a practice, but before the negotiations were quite completed he returned to Cork for a short holiday. The fight with the clubs had then just commenced, and Dr. O'Sullivan's relatives, anxious to have him at home, urged him strongly to accept the club terms, which he did. Readers of THE LANCET will recollect that snowballs were thrown at him by some students of the College, and that the affair was afterwards the subject of an investigation at the police-court. The students, as clearly appeared by the evidence, had only paid him the same unpleasant attention that had been meted out to many other citizens, but he, knowing he occupied an invidious position, believed the attack to be more or less preconcerted and he struck one of the snowballers with a stick. Legal proceedings followed. The clubs were anxious to make capital out of what no doubt was a most objectionable form of sport, but it is fair to Dr. O'Sullivan's memory and my very pleasant duty to be able to say that he had no desire to play the part of prosecutor of young men, some of whom had been at one time his fellow-students. In Dr. O'Sullivan the profession has lost a hard-working and able young man, whom circumstances and mistaken judgment placed in most regrettable opposition to the bulk of the profession in his native place, but to whom our recollection will recur not as the over-worked servant of the clubs, but as the popular, socially disposed, and able fellow-student.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Gonorrhœal Salpingitis.

AT the last meeting of the Société Anatomique M. Raymond exhibited a specimen of the above-mentioned disease. The specimen offered all the characteristics to which the speaker had already called attention in his thesis for the M.D. Paris—non-purulence of the ovary and purulence of the tubes. In the specimen shown the fimbriated extremity of the left Fallopian tube was completely closed, whilst the right tube communicated through the same extremity with the pus-laden pouch formed in the peritoneum. This pus and that of the corresponding tube, as well as that of the left tube, contained gonococci. Under the microscope the pus presented all the characters special to its gonorrhœal origin (in the acute stage)—viz., numerous leucocytes without epithelial cells,—in fact, the pus revealed the same characters as that collected from the blennorrhagic urethra. In cases, however, of salpingo-ovaritis due to the streptococcus, the pus contains only a few leucocyte associated with numerous desquamated epithelial cells. In streptococcic salpingitis abscesses of the ovary are frequent, as are also spreading peritoneal lesions.

An Insalubrious Children's Hospital.

Without counting the Hospice des Enfants-Assistés, we may say that Paris is endowed with two great children's hospitals: viz, the Hôpital des Enfants-Malades, in the rue de Sèvres, side by side with the Hôpital Necker—a general hospital—and the Hôpital Trousseau, situated in the rue de Charenton, not far from the Hôpital Saint-Antoine. The Hôpital Trousseau contains 472 beds, and its position in the midst of a dense working-class population keeps its wards and out patient rooms constantly filled. But its alleged unfitness for the purpose of ministering to the requirements of suffering childhood may be judged of by the following strictures passed on it by a municipal councillor, M. Baudin, at a recent meeting of the body to which he belongs: "Quant à l'hôpital Trousseau, je mettrai toute mon énergie à en obtenir la disparition; je vois tous les jours combien il fonctionne mal. C'est un véritable foyer d'infection, et les enfants y sont hospitalisés dans les conditions les plus déplorables, je dirai même les plus homicides. Quand on a demandé aux médecins des hôpitaux si des améliorations pouvaient être obtenues en conservant une partie des bâtiments actuels, tous ont déclaré que l'hôpital Trousseau devait être rasé"

La Guerre à l'Alcoolisme.

The frightful progress made by alcoholic abuse in France is only too apparent to the wideawake observer, and the authorities are beginning to be alive to the warning uttered by the Academy of Medicine during a recent discussion on the subject. Knowing well that early impressions are the most durable, the Ministry of Public Instruction appointed a Commission to report on the most efficacious means calculated to preserve *la jeunesse française* from falling into bad alcoholic habits. The Commission recommends the issuing of a Ministerial circular addressed to schoolmasters, wherein attention is called to the immense importance of the subject, and inviting them to do their utmost to influence their charges against such a noxious habit. It is suggested that a temperance manual, written by recognised authorities, be supplied to schoolmasters in order to serve as guides to them in the preparation of their lectures on the subject. In superior and normal colleges four or five annual lectures on alcoholism will be delivered by medical men. This excellent campaign will be pursued in girls' as well as in boys' schools.

Death of Professor Baillon.

The sudden death, on the 18th inst., is announced of Professor Baillon, who has since the year 1867 filled the chair of Botany and Natural History at the Faculty of Medicine. The deceased was aged sixty-seven years. He was a most accomplished botanist, and a recognised authority. Like many another eminent man, he was, however, as an examiner held in great dread by students, and many are the blank looks I have seen on the faces of aspirants at the *premier doctorat* at the prospect of having to face Professor Baillon. The late Professor Robin, the histologist, shared the same reputation. But it must, in fairness to these eminent teachers, be recollected that young students are frequently unjust in their appreciation of the qualities of examiners, who discharge their duties conscientiously if somewhat rigidly.

French Mineral Waters.

The Minister of Public Works informs us that there are at present being worked 1044 springs in France yielding mineral waters. Alkaline springs head the list, there being 358. Then come sulphur springs (318), saline (219), and chalybeate (149). The richest department in mineral springs is the Puy-de-Dôme, that district containing ninety-six springs in full working order. There are only twenty-three departments which are not endowed with springs. These different watering-places were visited last year by an aggregate of 600 000 persons.

(FROM OUR OWN CORRESPONDENT.)

The Cholera Virus and its Antitoxin.

IN the last number of the *Deutsche Medicinische Wochenschrift* Dr. Ransom together with Professor Behring published a remarkable communication on the cholera virus and its antitoxin. He states that injections of bouillon cultures of cholera bacilli have a typical influence on the temperature of guinea-pigs. A quantity of cholera bacilli, sufficient to kill the animal within twelve hours, makes the temperature first rise for about three hours and then fall till death. If the quantity of bacilli is not large enough to be fatal the temperature, after having fallen for some hours, suddenly rises again. In the most severe cases, where the animal dies within two, four, or six hours, the temperature falls immediately from the moment of the injection till death. From these facts Dr. Ransom concludes that a large amount of dissolved virus must be contained in the culture fluid. He even succeeded in finding the virus in a culture fluid from which he had previously removed the bacilli themselves, and injections of this fluid killed guinea-pigs much more quickly than when the bacilli were still in it. It was thereby proved that the virus was really present in a state of solution in the bouillon culture. Injections of the dissolved virus produce the same symptoms as injections containing bacilli; the animal grows faint, its fur becomes rough, its eyes lose their natural brightness, the skin becomes cold, general trembling ensues, and very soon the temperature falls. From the fluid Dr. Ransom has obtained also a solid substance which produced the same pathological symptoms as the diluted virus. This substance is of extreme virulence; 0·07 of a cubic centimetre kills a guinea-pig within twelve hours, and 0·1 even in fifteen minutes, but when given by the stomach it is innocuous. Dr. Ransom then immunised guinea-pigs, goats, and wethers by the well-known methods of Professor Behring. He states that there is an antitoxic substance in the blood of immunised goats. He made a 4 per cent. solution of the solid virus with the serum of immunised goats, injected this into guinea-pigs, and found that the animals survived even if 0·25 gramme of the solid virus were injected. The antitoxin is efficacious against both the fluid virus and the cultures of cholera bacilli. The blood of goats which have not been rendered immune has no effect at all. If simultaneous injections are made of virulent bacilli into the peritoneal cavity and antitoxin under the skin the animals survive; the same is the case when the serum is previously injected.

The Antitoxin Treatment of Diphtheria.

At the last meeting of the Society for Internal Medicine, before the commencement of the summer holidays, Professor Eulenburg gave a short account of the collective investigation on the antitoxin treatment of diphtheria. There were 10,240 cases reported from hospitals and from practitioners in all parts of the empire. Of 5790 patients treated with the serum 552 (= 9·5 per cent.) died; whilst of 4450 cases treated by other methods 652 (= 14·7 per cent.) died. In regard to age it was stated that patients under two years had a mortality of 21·7 per cent. when treated with antitoxin, and of 39·7 per cent. when treated without it; from two to ten years of age the corresponding mortalities were 8·8 per cent. and 15·2 per cent. respectively. These figures only confirm what has long been known to the majority of medical men; but general astonishment has been caused by the communications of Professor Eulenburg on the results in the case of patients above ten years of age. The death-rate of the antitoxin cases in this category even exceeded a little that of the other patients, the figures being 4·1 per cent. for antitoxin and 3·8 per cent. for the other methods. When antitoxin was used on the first or second day of the illness the mortality was only 4·2 per cent., but when its employment was delayed beyond this the mortality rose to 16·8 per cent. The investigation was closed on April 1st, but will be resumed.

The Health Resorts of the Crimea and the Caucasus.

After Professor Eulenburg's remarks Professor Leyden read a paper on the Health Resorts of the Crimea and the Caucasus. He visited these regions both on the occasion of the last illness of the late Emperor of Russia and subsequently when he was summoned to attend the Crown Prince at his summer residence at Abbas Tuman. Odessa was the first place to which he directed the attention of the audience, as being both a great commercial town and also a resort of bathers. The Black Sea contains very little salt, but near Odessa there is a kind of lagoon, where the water is calm and the proportion of salt is rather higher. Ample facilities for taking mud-baths are provided there. From Odessa Professor Leyden went to the Crimea. The northern coast of this peninsula is very plain, but the southern coast is one of the finest in the world, and by reason of its climate must be regarded as a first-rate health resort. High mountains protect this coast from the northern winds, so that the climate is very like that of the Italian Riviera, although of course the vegetation there is not so exuberant as that by the Mediterranean Sea. The mean temperature lies between that of the Riviera and the Italian lakes. The months of September and October are the most suitable for patients, especially for those who are phthisical; the spring is rather wet, and in winter there are many foggy days. In summer all parts of the south coast are used for bathing. The most fashionable place is Yalta, where about 7000 visitors assemble yearly. The country here offers ample opportunity for pleasant trips to the mountains. Near Yalta is the castle of Livadia, the favourite summer residence of the late Emperor. In speaking of the Caucasus Professor Leyden first mentioned Abbas Tuman, where the Crown Prince usually stays during the summer. It is situated about 1300 metres above the sea-level in a narrow valley enclosed by high mountains, so that the duration of sunshine there is comparatively limited, being only four hours at the period of the shortest day. The best time for phthisical patients is June and July; the autumn and winter are very rainy, but there is hardly any fog all the year round. In Abbas Tuman there are also hot springs which are used in three different degrees of warmth for the well-known Russian baths. The water is also employed for inhalations and douches. The accommodation for visitors is good, but the place is not so attractive as Berjoin, which is situated some miles from Abbas Tuman. Professor Leyden also visited the town of Tiflis, the capital of the Caucasian provinces; its hot springs are not used by any patients. This town is remarkable for the great variety of its inhabitants—Armenians, Tartars, Russians, Georgians, and other nationalities the names of which one scarcely ever hears. Not less than forty languages are spoken there. Tiflis, Professor Leyden remarked, must be an excellent place for women desiring to marry, as the number of men is four times that of the women. In Eryvan, a town of about 50,000 inhabitants, there were but two medical men—one military, the other civilian. It seems that the population must be extremely healthy, as the only civilian practitioner of the place enjoys also the dignity of mayor. At the end of his address Professor Leyden pointed out that the Caucasus possesses an enormous number of natural springs of every kind—sulphurous, ferruginous, thermal, and others—which of course might be of great therapeutic value. But as there is, some places excepted, hardly any accommodation for patients, and as travelling is in these regions rather laborious, it is not possible to make use of them. Professor Leyden, who spoke not only as a medical man but also as a traveller, was listened to with close attention, and the society then adjourned till the month of October.

July 22nd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Pellagra.

WHAT yellow fever is to the shores of the Caribbean, what the *plica Polonica* is to the banks of the Vistula, what cholera is to the delta of the Ganges, pellagra is to Upper Italy watered by the Po. True, it occurs in other quarters of the peninsula, but it appears in progressively diminishing force as one passes from the Alta Italia to the central and southern provinces, while in Upper Italy itself it is much less common in Piedmont than in Lombardy, and much less in Lombardy than in the Venetian territory. From the synoptical table compiled by the Direzione Generale della Statistica of 1886 I find that of the number of conscripts affected by pellagra the district of Padua contributed 13,834; of Treviso, 13,330; of Udine, 7844; of Brescia, 5266; that the district of Florence supplied 316; of Lucca, 170; of Pisa, 64; and of Rome, 29;

Digitized by Google

while the contribution of the Neapolitan and Sicilian districts was *nil*. In keeping with the above statistics the Venetian territory furnished 55,881 pellagrosi, Lombardy 36,630, and Piedmont 1328. In the years 1879 and 1881 the Direzione Generale dell' Agricoltura summed up the pellagrosi throughout the kingdom as at 97,855 in the former year and 104,067 in the latter. So that the endemic, instead of diminishing, seems to advance *pari passu* with the population—a result which may be explained by the still prevailing uncertainty as to its etiology and the consequent failure of prophylactic legislation. On the other hand, the curative, or I should rather say palliative, treatment now practised on the pellagrosi marks a decided improvement, lowering the mortality from 3390 in 1881 to 1698 in 1884—a fact still further confirmed by the hospital returns, according to which, of the 6025 treated during 1883 in the civil hospitals 923 died, while of 6944 treated in 1884 the deaths were only 780. A less satisfactory result appears in the development of madness due to pellagra—the *phrenosis pellagrosa* of Italian classification—the 1348 subjects to this form of mania in 1877 having steadily risen till in 1883 they numbered 1746. I have said that hygiene has not made up its mind as to the etiology of pellagra, though there is a steadily growing consensus of opinion that the consumption of unsound *gran turco* (maize) is the most powerful factor in its genesis. Misery, involving insufficient alimentation derived from a too unvaried diet, still, however, finds acceptance as its principal cause, and that, too, among sanitarians who come most in contact with the peasantry among whom it is endemic. But the only satisfactory way of solving the difficulty—that of tracing it historically to its first appearance at the close of the sixteenth century and determining the conditions under which it arose and continued, intensively as well as extensively, to develope—has not yet been attempted with the required learning, literary as well as hygienic; pending which, Italian State Medicine concentrates itself on minimising the circumstances favourable to its inception, while encouraging the palliative treatment above referred to. This, as conducted in the so-called Pellagrosarii (special hospitals for the pellagrosi), has its most typical, as well as successful, exemplar in the Lombard town of Inzago, where the Asilo di Pellagrosi, or Pellagrosario (already described in THE LANCET), has recently issued its annual report. From this most interesting document, entitled "Relazione sull' Andamento dell' Istituto dal 1° Ottobre, 1894, al 28° Marzo, 1895," a document which does great credit to its compiler, Dr. Giuseppe Fritz, director of the institution in question, I learn that within the twelvemonth 331 peasants labouring under the disease were admitted; that all of them, their ages ranging from twelve to twenty-eight, were children of pellagrose parents; that they entered in a prostrate condition, a prey to convulsions and hallucinations, often tending to suicide; while suffering from the epidermic lesions, the erythematous outbreaks, the fetid perspirations, the hypertrophy of the nails, the many signs of deep-seated trophic disturbance characteristic of the disease, and that, under treatment, all of them, with two exceptions, were so far rehabilitated physically and mentally as to return to the industrial life they had had to quit. Side by side and hand in hand with the dietetic and therapeutic regimen went steady occupation at various handicrafts, the females doing needlework, shoemaking, and straw-plaiting, and the males being employed in carpentry and outdoor labour—some of them being initiated in scientific agriculture and elementary hygiene. In fact, lectures to the number of 120 were given in these subjects and were fairly well appreciated by not a few of the auditors—sufficiently mastered by some of the exceptionally intelligent. Dr. Fritz demonstrates the value of steady, progressive, continuous work as an adjunct to medical treatment, correcting as it does the brain rust, the paresis of the cerebral energies which idleness even in the healthy always tends to induce. These poor males and females, none of them middle-aged, many of them mere boys and girls, return to peasant life not only relieved of their malady and physically rehabilitated, but intellectually and morally equipped with resources over and above their special agricultural *métier*—a comfort to themselves, a support to their parents, and an example to their neighbours. Milan, I understand, contributes handsomely to the institutions of which Dr. Fritz's at Inzago is a typical specimen, and the return it has had for its philanthropic liberality ought to encourage not only it but its sister towns to throw increased energy into the beneficent work.

Obituary.

JOHN PETER LYONS, L.F.P.S.GLASG., L.M., L.R.C.P. AND S.EDIN.

ASSISTANT COLONIAL SURGEON, HEALTH OFFICER, AND DISTRICT COMMISSIONER, GOLD COAST COLONY.

THE recent wave of unhealthiness on the Gold Coast has numbered among its victims no less than three medical men, who have succumbed within a period of six months from the pernicious effects of the climate while in the discharge of their duties. The deceased officer who is the subject of this notice was the son of Daniell Lyons, surgeon, of Clare Castle, co. Clare, and, after obtaining his diplomas in 1890, acted as resident assistant to Dr. Counsellor of Whalley, by whom he was held in the highest esteem and regard. In the early part of 1893 he left Dr. Counsellor to take up an appointment as an assistant colonial surgeon in the service of the Gold Coast Colony. Here he served at Accra, Ada, Kwitta, and Cape Coast, at which last station he fell ill of the fatal form of fever then prevalent, was invalided to the Canaries on May 10th, but died at sea the following day and was buried at Axim. Mr. Lyons held the dormant commission of a district commissioner of the Gold Coast Colony and acted as health officer of the several districts in which he served. In social life he endeared himself to all by his unostentatious, warm-hearted, good nature, and in his professional career both at home and abroad he won the confidence and esteem of his patients by his cheerful disposition, kindly manner, and firm resolution. In his despatch to the Secretary of State for the Colonies the Governor of the colony states in reference to the deceased officer: "He was one of the most skilful and popular officers we had, and by his death a vacancy that will be difficult to fill has been caused in the department. During the late serious epidemic of sickness at Cape Coast he was for nearly all the time the only medical officer there, and the severe physical and mental strain to which he was subjected no doubt had reduced his resisting power so much that when he himself was attacked he fell an easy victim to the deadly fever."

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the under-mentioned subjects:—

Surgery.—J. S. Challice, London Hospital; H. H. Thomas, Charing-cross Hospital; A. E. Lovitt, London Hospital; C. A. E. Coulthard, St. George's Hospital; M. White, St. Thomas's Hospital; H. G. Jones, St. Mary's Hospital; H. C. Watt, Liverpool; H. England, Sheffield; F. J. Gaine, Cambridge and St. Mary's Hospital; H. C. T. Dalton, Charing Cross Hospital; J. Cryer, Manchester; and C. W. Moorshead, Guy's Hospital.

Medicine, Forensic Medicine, and Midwifery.—W. B. Maurice, St. Mary's Hospital; F. W. Gale, St. Bartholomew's Hospital; W. S. Dibbs, Leeds Hospital; C. M. Beadnell, Guy's Hospital; Ethel M. Gough, London School of Medicine for Women; and H. C. Watt, Liverpool.

Medicine and Forensic Medicine.—C. C. Preston, Manchester, and P. S. Kesteven, St. Bartholomew's Hospital.

Medicine and Midwifery.—H. W. Ramsay, St. Mary's Hospital.

Medicine.—F. E. H. Keogh, St. Mary's Hospital; R. D. Cox, St. Mary's Hospital; and T. H. P. Peers, Charing Cross Hospital.

Forensic Medicine and Midwifery.—A. P. Eldred, St. Mary's Hospital; A. W. Silver, Charing-cross Hospital; and H. England, Sheffield.

Forensic Medicine.—G. S. Taylor, Manchester; A. E. De Vall, Birmingham; and J. M. A. Lamb, London Hospital.

Midwifery.—G. A. Child, St. Thomas's Hospital.

To Messrs. Challice, Thomas, Lovitt, Maurice, Gale, Dibbs, Beadnell, Watt, Kesteven, Keogh, Cox, and Peers was granted the diploma of the society entitling them to practise Medicine, Surgery, and Midwifery.

UNIVERSITY OF GLASGOW.—The following have passed the Final Professional examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

A.—Candidates who took Pathology in Final Professional Examination:—John Carson Abbott, Thomas Armstrong, Francis James Barker, M.A., Thomas Baxter, Alexander Blair, Henry Albert Böedeker, Thompson Campbell, Vivian Ernest Chang, Henry Davies, William Donaldson, Richard John Edwards, Samuel English, James Findlay, Robert Mackechnie Fraser, M.A., Walter Graham, William Hay, B.D., John Affleck Hope, Albert Barnes Hughes, George Jubb, William James Kerr, William Duncan Miller, Duncan M'Donald, William Jones Mackinnon, Moses Neil MacLay, Farquhar Macrae, Edward James Primrose, M.A., John Rankin, and James Sandilands.

B.—Candidates who passed Pathology in third professional examination:—James Adam, William Alexander, William Allan, Arthur

Digitized by Google

Roland Anderson, John Anderson, John James Stevenson Anderson, John Lindsay Anderson, William Stephen Baird, Robert Brownlee Barr, Thomas Bell, Henry Broom, William Burns, Samuel Capie, William Clow, M.A., B.Sc., Frederick Burdett Cormick, Samuel Donaldson Cowan, M.A., John Cumming, John Divine, John Hannay Douglas, Matthew Dunning, Joshua Ferguson, M.A., William David Findlay, Albert Alfred Finkelstein, James Liddell Forrest, James Forster, James Reid Foulds, Andrew Fleming Galloway, Thomas Cleator Garrett, John Gillan, M.A., James Drummond Graham, John Alexander Graham, William Grove, Arthur Holt, Robert Howie, Gavin Dalzell Hunter, James Jack, John William Jackson, David Kerr, David Connor Kirkhope, John Kirkwood, William Henry Lang, B.Sc., William Lawson, David Lewis, John Dunlop Louttit, Robert King Miller, John Miller Woodburn Morrison, George Mowat, Adam Cubie Muir, James Andrew Dixon Mulholland, Donald Munro, James M'Cash, Daniel M'Coll, William Milligan M'Cormick, Lewis MacLachlan, Hugh M'Laren, William Macleod, George M'Pherson, M.A., Archibald Russell Oliver, Henry Alexander Pattullo, John Broadfoot Rae, John Neil Robertson, William Scobie, B.D., James Smith, Thomas Orr Spiers, James Sproull, Alexander Stevenson, Hugh Stevenson, Alexander Stewart, Alexander Hamilton Stewart, James Stewart, James Stirling, Hugh Wright Thomson, Joseph Milton Thornley, Charles Kirk Toland, Ernest Alexander Walker, M.A., Henry Allan Watson, M.A., Malcolm Watson, Frederick Wolverson, Archibald Young, B.Sc., and John Young (Glasgow). Women candidates—Emmeline Marie Stuart.

EXHIBITION OF OLD CHINA.—An exhibition of old china, glass, pottery, antique relics, and curios of every description will be held at the Royal Aquarium in September and October next, and the directors appeal for contributions to the loan collection.

PRESENTATION.—Mr. George H. Heald, L.R.C.P. Edin., M.R.C.S. Eng., divisional police surgeon at Leeds, has been the recipient of a purse of gold subscribed by members of the City Police Force, in appreciation of his efficient instruction on first aid to the classes in connexion with the St. John Ambulance Association.

ON the occasion of the address on Art in Relation to Anatomy, to be given during the meeting of the British Medical Association, by Professor W. Anderson, in the Examination Hall on Wednesday next, the subject will be illustrated by a collection of anatomical works, with engravings, from the fifteenth century to the present day, with lantern reproductions of selected examples of ancient statuary and anatomical cuts.

INSTITUTE OF CHEMISTRY. — The following gentlemen passed the examinations for membership held on July 2nd to July 5th, 1895:—Alexander Frankenbacher Fuerst (Fellowship), Ernest Robert Andrews, Charles Kepler Barnes, Augustus Charles Bodey, James Girdwood Bowie, Horace Edgar Bowles, John Buchanan, James Kerry Burbridge, Cecil Henry Desch, Frederick Robertson Dodd, Thomas Guthrie, Charles Alexander Hill, Henry Reginald Hirst, Herbert King, Loxley Meggitt, Howard Charles Ridding, John Blair Warden, Frederick Malcolm Wharton, George Henry Woollatt, and Walter Robins, B.Sc. Lond. (Associateship). The examiners were Professor Dunstan, F.R.S., and Mr. Otto Hehner.

SAD DEATH OF THE MATRON OF THE ROYAL INFIRMARY, NEWCASTLE-UPON TYNE.—Miss Ross was found in a dying condition in her bedroom on Monday morning last. She said she had swallowed a solution of bichloride of mercury in the operating theatre at 3 A.M., and soon after making this statement died, at about 9.30 A.M. An inquiry was held by the coroner on Tuesday, when the following verdict was returned: That death arose from poison taken by Miss Ross, her mind at the time being deranged. Miss Ross had been matron for some four years, and previously had filled two subordinate posts in the nursing department of the Royal Infirmary. Altogether her connexion with the infirmary extended over a period of some twelve years. She was universally respected, had the full confidence of the staff and the affection of the nurses and patients. No one could have been more devoted to her duty. No one had the welfare of the institution more at heart than she had. The post of matron to a large hospital must always be a trying and anxious one, and there is good reason for believing that Miss Ross felt the strain, and that a recent occurrence in connexion with the rearrangement of nurses was a source of trouble and unhappiness to her. How far this little cloud—for really it was nothing more—contributed to her lamentable death can only be a matter of conjecture, but that she took it very much to heart is very well known. The body was removed to and buried at Embleton, a short service having previously been conducted in the infirmary chapel by the chaplain.

ROYAL BRITISH NURSES ASSOCIATION. — The annual meeting of this association was held on Wednesday last under the presidency of Sir James Crichton-Browne. The report for the year showed continuous satisfactory progress. The presence of Princess Christian was made the subject of a vote of thanks, proposed by Sir Spencer Wells and seconded by Dr. Buzzard. Her Royal Highness, who was received with acclamation, proposed a vote of thanks to the chairman.

BANK HOLIDAY RAILWAY ARRANGEMENTS.—For holiday-makers visiting Holland and the Amsterdam Exhibition the Great Eastern Railway Company will issue cheap return tickets on Friday and Saturday, Aug. 2nd and 3rd, *vid* Harwich and the Hook of Holland. Special facilities are also offered to passengers visiting Germany by the same route, particularly for those travelling direct from the northern and midland counties, whence they can start in the afternoon, or from London in the evening, reaching the chief Dutch cities early next morning, Cologne in the afternoon, and Berlin in the evening, by through carriages, this being the cheapest route to Germany. Short Belgian tours, including Brussels (for Waterloo), the Ardennes, and the picturesque Flemish cities have been arranged *vid* the Harwich-Antwerp route. Passengers leaving on Friday or Saturday, Aug. 2nd or 3rd, reach the Ardennes next afternoon, and can return on Monday in time to reach London early on Tuesday morning. The General Steam Navigation Company's steamers will leave Harwich for Hamburg on July 31st and Aug. 3rd, returning Aug. 4th and 6th.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

HODGSON, JOHN, M.B. Lond., M.R.C.S., has been reappointed Assistant Surgeon to the Oldham Infirmary.

HORROCKS, HERBERT, M.D. Lond., has been appointed Resident Medical Officer at the Hospital for Consumption and Diseases of the Chest, Brompton, S.W., vice Ballance, resigned.

MACLENNAN, FELIX PRYOR, M.B., C.M. Aberd., has been appointed Medical Officer for the Parish of Assynt and the Quoad Sacra Parish of Stoer, N.B.

MCLEAN, CHAS. J. R., M.D. Edin., D.P.H., has been reappointed Medical Officer of Health to the Yeadon Urban District Council.

RUSSELL, J. L., M.B., C.M. Edin., has been appointed Medical Officer for the Cornholme Sanitary District of the Todmorden Union.

THOMSON, FRED. H., M.B., C.M. Aberd., D.P.H. Lond., has been appointed, pro tem., Medical Superintendent of the Gore Farm Hospital.

WOOD, T. JASON, M.D. Lond., M.R.C.S., L.R.C.P., has been appointed Honorary Assistant Medical Officer to the Bradford Infirmary and Dispensary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ANCOATS HOSPITAL, Manchester.—Resident Junior House Surgeon. Salary £60, with board and washing.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL, 62, Chandos-street, W.C.—Lectureship on Physiology. A minimum of £300 a year is guaranteed for the teaching of physiology, together with a grant for working expenses.

DURHAM COUNTY ASYLUM.—Pathologist and Junior Medical Officer. Salary £100 per annum, with board and lodging. Applications to the Superintendent, Durham County Asylum, Winterton, Ferryhill.

INFIRMARY OF THE CITY OF LONDON UNION.—Assistant Medical Officer at the Infirmary of the Union, situate in the Bow-road. Single, or widower without children. Salary £160 per annum, with furnished apartments at the infirmary, rations, and washing. Applications to the Clerk to the Guardians, 61, Bartholomew-close.

LINCOLN COUNTY ASYLUM, Lincoln.—Assistant House Surgeon for six months. An honorarium of £10, subject to the approval of the weekly Board, and board, residence, and washing provided.

LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant House Surgeon for six months. Board and lodging provided.

METROPOLITAN ASYLUMS BOARD.—Assistant Medical Officers at several of their Fever and Small-pox Hospitals, unmarried. Salary and emoluments assigned to the offices are £160 per annum, rising yearly by £20 to £200 per annum, with board, lodging, attendance, and washing. Applications to the Clerk to the Board, offices, Norfolk House, Norfolk-street, Strand, W.C.

Digitized by Google

MORPETH DISPENSARY.—House Surgeon, unmarried. Salary £120 per annum, with furnished house, coals, and gas. Applications to Mr. N. J. Wright, Morpeth, Northumberland.

PARISH OF CAMBERWELL, London.—Medical Officer for the Infirmary at Havil-street, Camberwell, and the Workhouse. Salary £350 per annum, increasing £25 annually to a maximum of £400, with unfurnished house, water, gas, and coals. Applications to the Clerk to the Guardians, 29, Peckham-road, S.E.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon. Board, residence, and washing provided.

ROYAL EAR HOSPITAL, Frith-street, Soho-square, London.—Assistant Surgeon.

ST. BARTHOLOMEW'S HOSPITAL, London.—Physician and an Assistant Physician.

ST. LUKE'S HOSPITAL, London, E.C.—Clinical Assistant for six months. Board and residence provided.

STOKE NEWINGTON, CLAPTON, WEST HACKNEY, AND DALSTON DISPENSARY, 108, High-street, Stoke Newington, N. — Resident Assistant House Surgeon. Salary £50 per annum, with board and lodging.

SURREY DISPENSARY, Southwark, S.E.—Resident Medical Officer. Salary £120 per annum, with furnished apartments, coal, gas, and attendance. Applications to the Secretary, 53, Borough High-street, Southwark.

Births, Marriages, and Deaths.

BIRTHS.

FISHER.—On July 22nd, at Sheil-road, Liverpool, the wife of Alex Fisher, M.B. Edin., of a daughter.

JACKSON.—On July 18th, at Kirk House, Hedon, the wife of John Lowthian Jackson, M.B. Edin., of a daughter.

MCKENZIE.—On June 26th, at Berea, Durban, Natal, the wife of Archibald McKenzie, M.D. Edin., of twin daughters.

ROCHE.—On July 11th, at the Barracks, Newport, Mon., the wife of Surgeon-Major E. A. Roche, A.M. Staff, of a son.

SCHOLEFIELD.—On July 17th, at Eastcomb-villas, Blackheath, the wife of R. E. Scholefield, M.B. Oxon., of a daughter.

TRAVERS-SMITH.—On July 21st, at Trevose, Beckenham-road, the wife of V. E. Travers-Smith, M.D. Dubl., of a daughter.

MARRIAGES.

ANDREWES—HAMER.—On July 25th, at Holloway Congregational Church, Dr. Frederick William Andrewes, of 35, Welbeck-street, W., son of Charles James Andrewes, J.P., of Reading, to Phyllis Mary, daughter of John Hamer, J.P., of 69, Dartmouth Park-hill, N.W.

HICKMAN—THOMPSON.—On July 16th, at St. Martin's Church, Brampton, Cumberland, Henry Richard Belcher Hickman, M.A., M.B. Oxon., only son of William Hickman, F.R.C.S., of Harley-street, Cavendish-square, to Margaret Kate, only surviving daughter of the late James H. Thompson, of Warren Bank, Brampton.

PRANGLEY—DOMMETT.—On July 18th, at St. Paul's Church, Upper Norwood, by the Rev. W. H. Graham, assisted by the Rev. C. W. Prangley (cousin of the bridegroom), Henry John Prangley, L.R.C.P. Lond., M.R.C.S. Eng., of Tudor House, Anerley, only son of the late John Peard Prangley, of Heytesbury, Wiltshire, to Clara Elizabeth, youngest daughter of Charles William Dommett, of Moorfield, Anerley. No cards. At home Sept. 9th, 10th, 11th, and 12th, 3 to 6 P.M.

SKINNER—FREEMAN.—On July 17th, at the Church of St. Mary Abbotts, Kensington, Ernest William Skinner, M.D. Edin., of Bank House, Rye, Sussex, to Isobel Katharine, eldest daughter of George Mallows Freeman, of Phillimore-gardens, Kensington.

SMITH—FISHER.—On July 23rd, at Christ Church, Brondesbury, Ernest Newlyn Smith, M.D. Lond., M.R.C.S., of Forth Lodge, Willesden-green, to Charlotte, eldest daughter of Henry Fisher, of Carrick, Willesden-lane.

STRAIN—SAVORY.—On July 18th, at Palgrave, Suffolk, William London Strain, M.B. Glasg., of São Paulo, Brazil, to Dorothy Maud, second daughter of the Rev. Ernest Lloyd Savory, Rector of the parish.

THOMSON—FRERE.—On July 23rd, at Holy Trinity Church, Marylebone, Herbert Campbell Thomson, M.B. Lond., eldest son of Dr. D. Thomson, of Luton, to Constance Emily Temple Frere, fourth daughter of the late Robert Temple Frere, of Harley-street.

USHER—MEYLER.—On July 6th, at Laurel Lodge, Dundrum, county Dublin, Isaac William Usher, Surgeon, Tudor House, Dundrum, to Rosie, youngest daughter of the late Captain Meyler, Dundrum House.

DEATHS.

GOODFELLOW.—On July 19th, at Paignton, Devonshire, Stephen Jennings Goodfellow, M.D., F.R.C.P., in his 86th year.

JACOBSON.—On July 17th, at Sleaford, Thomas Edmund Jacobson, M.R.C.S., L.R.C.P., L.S.A., aged 65 years.

NOAD.—On July 20th, suddenly, George William Noad, M.D. St. And., of Upper Tollington-park, N., in his 67th year.

OWEN.—On July 20th, at 16, Scarsdale-villas, Kensington, in his 84th year, William Buy Owen, L.R.C.S. Edin., L.S.A., formerly of Finchingfield, Essex, and of Cleveland-square, Hyde Park, W.

STEWART.—On July 21st, at Russell-square, W.C., John Macpherson Stewart, Medical Student at University College Hospital, and younger son of the late John Stewart, H.M. Indian Navy, aged 25 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the half-year ending June, which was given in the number of the 29th ult., completed the first volume of the year 1895. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1895 are now ready. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s*.

To be obtained on application to the Manager, accompanied by remittance.

THE LANCET AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

"LORD BYRON'S LAMENESS."

To the Editors of THE LANCET.

SIRS,—In answer to the inquiry of "M.B., C.M." in THE LANCET of July 20th I beg to say that a communication from the pen of the late Dr. Chalmers, accompanied by a pair of woodcuts of casts of Lord Byron's foot, appeared in THE LANCET about twelve years ago. I have not the exact date, but it can be easily found by looking through a file of THE LANCET from 1880 to 1885. I remember getting the wood blocks made for Dr. Chalmers during the time I was his assistant, between those years. I am, Sirs, yours truly,

Vincent-square, S.W., July 22nd, 1895. LAUNCELOT ARCHER.

*** The letter with woodcuts of which Mr. Archer has kindly reminded us will be found in THE LANCET for 1883, vol. i., p. 975. Another communication about Hunter is in the same volume, p. 1023.—ED. L.

Aspirant will find a list of the principal appointments held by medical men at p. 20 and following pages of the Medical Directory for 1896. Vacancies are almost always advertised both in the medical and local lay press, and a special column under the heading "Vacancies," giving a summary of all such advertisements appearing in our columns, is published in THE LANCET week by week.

AN ADVERTISEMENT OF A HOSPITAL.

THE *Times* of July 23rd, 1895, contains the following advertisement:—

ANYBODY in LONDON having spare time on Monday, 22nd, or Tuesday, 23rd July, is INVITED to VISIT the POPLAR HOSPITAL for ACCIDENTS between 2 and 7 o'clock.

Newly built. Newly fitted. No debt.
No horrors. No infection.

Best Way.—Drive or bicycle, 45 minutes from West-end.
Another Way.—Blackwall Omnibus from Piccadilly-circus, 75 minutes.
Another Way.—Train to Aldgate, thence by yellow tram.

We do not think this a very fitting advertisement, inasmuch as it contains remarks that might tend to keep charitable visitors away from other hospitals. Moreover, it is not dignified, and savours too much of the method of advertisement of "Richardson's Show" or a Cheap Jack. Enterprise should ever be tempered by taste.

Trouville.—Without judging of the merits of the difference between our correspondent and his principal, we should not advise him to take any legal steps to demand more than a month's notice. On the face of the documents (letters) this was the kind of arrangement to which he seemed to consent and, in the absence of any other form of contract, by which he would be bound.

F.M.—We think the junior should receive his share of the receipts and moneys owing at the branch prior to the dissolution. He would act wrongly if he persisted in staying. The details should be amicably arranged.

"ALLEGED TOUTING BY A PUBLIC VACCINATOR."

To the Editors of THE LANCET.

SIRS,—In reply to your comments in THE LANCET of July 20th I write to make an important correction. You say that my letter of July 1st "places a different complexion upon the matter." Do you mean a complexion different from that given by Mr. Eccles? In that case I reply that it certainly does. Or do you mean a complexion different from that given in the letters from Dr. Slane and myself, already in your hands before I wrote that letter of July 1st? In that case I reply that it certainly does not. Throughout all the correspondence we have given only one complexion to the matter. The different complexion which you now see, but never before saw brought out in any of the letters submitted to you, has been given by your importing of the words "with regard to defaulters," which with very little trouble you will soon satisfy yourself have not been used by me. Nowhere in any letter have I gone so far as to speak of the patients referred to by Mr. Eccles as defaulters. In view of this correction your plea in extenuation of your severe censure of Dr. Slane, "that it was not previously brought to your notice," and "that it was not brought out in any of the previous letters submitted to you," "that his visit had been made only in consequence of representations made to him by the vaccination officer with regard to defaulters," is not relevant to the evidence before you. What was really brought out in those letters, in addition to the emphatic denial of the charge of touting, and reiterated previously to July 1st, for the information of Mr. Eccles and yourself, was the fact that Dr. Slane was instructed by the authority to call upon all the cases referred to by Mr. Eccles and his witnesses, and was furnished with a list of the names for the purpose. See Dr. Slane's letters of May 26th and June 18th. My last letter, commenting *seriatim* on your remarks in your issue of June 29th, repeats this information. It does not seek to rebut the charge of Mr. Eccles on the ground that the patients of Mr. Eccles were defaulters. It deals with the evidence placed in your hands with my letter of June 19th, and asks you to answer two straight questions, which in effect are, first, to justify Dr. Slane in an ample, generous manner in respect of the disgraceful charge which you have unjustly allowed to be made against him in your journal; and, secondly, to say whether, in view of the correspondence before you, you still adhere to your statement that Mr. Eccles "was perfectly justified in making his complaint." You aided Mr. Eccles in affixing an obnoxious name to a professional neighbour while he was yet ignorant of having given any cause of offence. With questionable haste and more than questionable morality you supplied Mr. Eccles with a weapon of retaliation outside the profession before you yet knew if the charge could be substantiated. Of this your client made premature use, and, in my opinion, vindictive use. And you justified him. Your comments throughout have been directed to Dr. Slane. Have you nothing to say to the part Mr. Eccles has taken in this matter? Since May 18th you have kept one party, the innocent one, in your pillory. Would it not be an act of justice to give the other now his turn according to his deserts—not vindictively, but for his better instruction in the first elements of applied morals? In your comments of the 20th inst. you are silent on the course Mr. Eccles has pursued in making his unfounded charge. Why do you show such tender reserve in his case while you have not spared hard blows to his neighbour, whom he has unjustly accused?

I am, Sirs, yours truly,
Driffield, July 22nd, 1895. J. LUMSDEN BELL.

*** We have again read the copies of the letters placed in our hands by Dr. J. Lumsden Bell. Dr. Slane's letter of May 26th contains nowhere the information that he "was instructed by the authority to call upon all the cases referred to by Mr. Eccles and his witnesses." Dr. Slane's letter of June 18th contains the words, "To your long details of your study of the Vaccination Acts I added the information you seemed to be ignorant of—that I had orders from the authority to call upon all whose names were supplied to me as living over two miles from my house." Unfortunately, Dr. Slane did not add, and we did not see, that these were "all the cases referred to by Mr. Eccles." Dr. J. Lumsden Bell's letter of June 19th contains the words, "He (Dr. Slane) had always confined himself strictly to the lines of his instructions." His letter of July 1st, being more explicit, "placed a different complexion upon the matter" by controverting Mr. Eccles and adding to Dr. Slane's communications a clearness that they had not previously possessed for us, though we seem not to have entirely understood him this time. We cannot admit that it was Dr. Slane's duty to visit every child born. He ought only to visit those beyond the statutory age reported to be in default; and surely this expression of opinion is relevant. We cannot see in our comments the animus that Dr. J. Lumsden Bell sees in them, though we deeply regret that we should have reflected in an unjustifiable manner upon Dr. Slane. We reported not on facts, but on alleged facts. We read carefully the correspondence submitted to us, and our comments were in accordance with our comprehension of it. When we believed ourselves to have been misinformed, we at once said so, and withdrew the offending epithet.—ED. L.

Mr. Stanley E. Ward.—Our correspondent would probably find the information he seeks in Hunter's Imperial Gazetteer. He might write to the Director-General of the Army Medical Department, 18, Victoria-street, Westminster, or to the India Office, and inquire whether there is any recent official publication bearing upon the subject.

HOUSE SURGEONS AND CORONERS' INQUESTS.

To the Editors of THE LANCET.

SIRS,—I had just completed my term of office as house-surgeon at Guy's Hospital on June 30th. On July 1st I was summoned to give evidence relating to a case that had died three days previously. The case, which I need not go into, raised a very important question, in consequence of which the evidence was of a detailed and lengthy character. The coroner adjourned the case for a week. In the meanwhile I had to refuse a remunerative locum tenency in the North of England, and had to take another instead in the suburbs. I had to pay my travelling expenses to London, and to spend nearly two hours in the court. The coroner asked me my opinion as an expert about evidence given by another medical man. Is he justified in putting any but questions as to facts? When I claimed my fee as being no longer an officer of the hospital, he regretted that the law of the London County Council did not allow it. Do you not think that it is time that means should be taken to remedy such an injustice, which is only too liable to recur?

I am, Sirs, yours faithfully,
July 12th, 1895. EX H.S.

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—There have been several letters of late in THE LANCET re the using of medical titles other than those to which the users are legally entitled. I think that to the general public the matter is of slight importance, it being very far from the case that the holders of the higher qualifications are the most successful practitioners, but from a strictly professional point of view it is a mean action to describe oneself on a brass plate by any other title than one's qualification warrants — yet how commonly it is done. In this neighbourhood we have an L.S.A. who puts "Dr. ——" on one plate and "Mr. ——, physician and surgeon," on another; an M.R.C.S., L.S.A., who calls himself "Dr."; and another M.R.C.S., L.R.C.P., who has "Dr. ——, physician, surgeon, and accoucheur." None of them do large practices.

I am, Sirs, yours truly,
July 23rd, 1895. M.R.C.S.

*** We have received many letters on this subject, a selection of which we shall print later.—ED. L.

MR. LUKE FILDES' "THE DOCTOR."

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me whether it is possible to obtain an engraving or other good representation of Mr. Luke Fildes' picture of "The Doctor," which was exhibited at the Royal Academy a few years since? I should like to know where it can be obtained and the price.

I am, Sirs, yours truly,
July 22nd, 1895. J. W., M.D.

*** The publishers are Messrs. Thomas Agnew and Sons, Art Publishers, 39B, Old Bond-street, W.—ED. L.

THE POST OF SURGEON ON THE CABLE TELEGRAPH SHIPS.

To the Editors of THE LANCET.

SIRS,—I shall take it as a very great favour if any of your readers will kindly give me some information concerning the post of surgeon on board one of the cable telegraph ships, the pay received, length of voyage, &c.

I am, Sirs, yours faithfully,
July 24th, 1895. H. A. B.

PRACTICE IN ALGIERS.

To the Editors of THE LANCET.

SIRS,—Will you or some of your readers kindly tell me whether it is necessary to have a French diploma to practise in Algiers?

I am, Sirs, yours truly,
Sea View, I.W., July 24th, 1895. A. B. C.

Digitized by Google

ELECTROLYSIS.

W. J. R.—The apparatus necessary comprises a constant-current battery, sufficient to give a current of four to five milliampères through the resistance of the body—i.e., about 3500 ohms,—the usual leads, a fine electrolysis needle with a make and break key in the handle, a pair of epilation forceps, and a pad for the indifferent electrode. Our correspondent will find every information in "Medical Electricity," by H. Lewis Jones, M.D. (London: H. K. Lewis).

Louis.—The queries are too vague to answer. The most suitable country must depend upon our correspondent's health, temperament, amount of capital, number of friends, and many other circumstances that will occur to him. If he will put to us some specific question and will give us full information we will afford him all the assistance in our power.

"THE CLIMATE OF THAYETMYO."

To the Editors of THE LANCET.

SIRS,—I have a friend on a visit here temporarily, on leave of absence from his duties in Rangoon, Burma, after two years' residence there. He tells me that he spent two nights in Thayetmyo a short time ago on his way to Mandalay, in Upper Burma. Thayetmyo is a fairly healthy up-country district, with good cold weather in November, December, and January. It is a jungle district, but there are hills (as you may see marked on the maps) 1686 feet above sea level within a short distance, but not available for residence. Thayetmyo is easily accessible from Rangoon, one day's journey—fifty miles by rail to Prome and twenty by good river steamer. Steamers run two or three times a week. It is a large native town, containing but a few Europeans—probably only twenty or thirty. The Indian hill stations are within four or five days' distance of Rangoon.

My friend is about to marry and take his wife to Rangoon, where he expects to remain a few years longer. There are so few English ladies out there—i.e., at Thayetmyo—that it is difficult to form an idea as to their health or that of children. He is not in the profession.

I hope this brief account of Thayetmyo will be of some use to "M.D." I am, Sirs, yours faithfully,

July 23rd, 1895. R. A.

*** Yule's "Mission to the Court of Ava" gives a variety of information about the climate &c. of the district between Rangoon and Ava.—ED. L.

CUM *v.* SINE CURRICULO DENTAL DIPLOMAS.

To the Editors of THE LANCET.

SIRS,—It will remove a considerable amount of doubt in the minds of many dental surgeons if you will be good enough to express an opinion upon the following.

A somewhat unusual case having been brought under A.'s notice, he requested that he might have a consultation, explaining at the time that he would be glad to meet any properly qualified practitioner. The name suggested was that of a dentist holding a *sine curriculo* licence, and A. declined the consultation, another name being substituted, which gave mutual satisfaction. A. holds that no surgeon or medical man would entertain for a moment the idea of meeting a diplomate or licentiate holding his licence under such circumstances (were that possible), and considers that dental surgeons should regard the matter from a similar standpoint. Is A. right? Yours faithfully,

July 15th, 1895. PERPLEXED.

*** Providing that the dentist holding the *sine curriculo* licence carried on his practice in a professional manner, we do not think that A. should have declined the consultation.—ED. L.

THE FIRST NUMBER OF "THE LANCET."

To the Editors of THE LANCET.

SIRS,—I have just noticed the advertisement in your issue of the 6th inst., offering £1 for a copy of the first number of THE LANCET, which must be complete *with its cover*. It would be interesting historically to know whether the advertiser has embarked, in his search for this *rara avis*, on a wild-goose chase, or whether Mr. Clarke is wrong in stating in his Autobiographical Recollections that the number in question had no cover. I am, Sirs, yours truly,

Paris, July 23rd, 1895. HISTORICAL.

AN IMPOSTOR.

To the Editors of THE LANCET.

SIRS,—Allow me to warn your readers against an American who professes to be a nephew of Professor Sayre of New York, and endeavours to borrow money as a temporary loan. Yours obediently,

July 23rd, 1895. CHIRURGUS.

*** A man called at our offices on Monday last, and tried to borrow a small sum to enable him to cable to his uncle in America. Doubtless this is the gentleman to whom our correspondent refers.—ED. L.

"WANTED, ADVICE ON HEALTH RESORTS."

To the Editors of THE LANCET.

SIRS,—Having had patients abroad for rheumatism and also nephritis, I should advise to your correspondent, "O. H.," Las Palmas, Grand Canary, as a good winter resort—equable climate, good hotels, and cheerful society and amusements. It is cheaper than Egypt, and the Santa Catalina Hotel has an agency in London. One patient who was at Corfu last winter does not recommend it. Yours truly,

July 19th, 1895. M.D.

A QUESTION OF PROPER PROCEDURE.

To the Editors of THE LANCET.

SIRS,—Can you give me some advice on the following point? A. is called to attend a lady as her regular adviser. The case is serious, and a consultant's opinion is sought. This from its gravity alarms the friends, who ask for a second general practitioner to watch the case in company with A. On the advice of A., B. is called, who happens to live nearer to the patient than A. For this and perhaps from fancied preference on the part of the patient, B. is frequently called to visit the patient alone for fancied and occasional dangers. He is also asked to prescribe, and a preference is shown for some of his prescriptions over those of A. How is B. to act? Is he to decline to visit and prescribe, or to prescribe only in A.'s absence? Yours faithfully,

July 22nd, 1895. P.

*** B.'s position is a very undesirable and difficult one. He can only do his best. Obviously he must take every opportunity of showing deference to A., by requiring his sanction wherever practicable to changes of treatment, and in every other way. On the other hand, A. must consider B.'s difficulties, and make allowance for them.—ED. L.

"PRACTICE IN NEW ZEALAND."

To the Editors of THE LANCET.

SIRS,—If your correspondent, "M.B. & C.M." who desires information concerning medical practice in New Zealand, will privately send me his address, I will be happy to supply him with some facts on which he may confidently rely.—I am, Sirs, yours faithfully,

ALFRED WRIGHT, L.R.C.P. ED., &c.

22, Steyne, Worthing, July 23rd, 1895.

Communications, Letters &c. have been received from—

A.—Dr. J. Althaus, Lond.; Mr. J. W. Arrowsmith, Bristol; Ancoats Hospital, Manchester, Secretary of; Aspirant.

B.—Dr. J. Braithwaite, Leeds; Dr. J. F. Bullar, Southampton; Dr. A. H. Buck, New York; Dr. F. Bagshawe, St. Leonard's-on-Sea; Sir Walter Besant, Edinburgh; Mr. R. D. Boyd, Glasgow; Mr. C. Birchall, Liverpool; Mr. W. G. Burcombe, Lincoln; Messrs. F. B. Benger and Co, Manchester; Messrs. Blondeau et Cie., Lond.; Messrs. Beadel, Wood, and Co., Lond.; British Institute of Public Health, Lond., Secretary of; British Medical Association, Lond., Secretary of.

C.—Dr. J. Cagney, Lond.; Dr. J. M. Clarke, Bristol; Dr. W. S. Colman, Lond.; Brig.-Surg.-Lt.-Col. W. H. Climo, Aldeburgh; Mr. G. L. Cheatle, Lond.; Mr. H. Chabot, Lond.; Cortland Wagon Co., Lond., Manager of; Charing Cross Hospital Medical School, Dean of; Commerial, Church, and Collegiate Agency, Director of; Cornwall County Council; Mr. A. Croly, Rathfarnham, co. Dublin; C. K., Lond.; Clitheroe, Lond.

D.—Dr. C. B. Duff, Lond.; Mr. W. Duke, Kirriemuir; Messrs. Dawson and Sons, Lond.; Messrs. Domeier and Co., Lond.

E.—Mr. C. B. Elliott, Geraldton, Australia; Empire Natural Stone Filter Co., Lond.; E. C. U., Lond.

F.—Dr. F. Fox, Strathpeffer Spa; Dr. T. Fisher, Bristol; Farlo, Reading.

G.—Dr. W. R. Gowers, Lond.; Dr. J. Grant, Wirksworth; Miss Galloway, Glasgow; Glasgow University, Secretary of; Mr. G. R. Grier, Lond.

H.—Dr. H. Harper, Nottingham; Dr. G. Herschell, Lond.; Dr. H. C. Highet, Singapore; Dr. T. W. Hime, Bradford; Dr. F. Hawkins, Reading; Mr. J. T. Hislop, Hampsthwaite; Mr. J. Heywood, Manchester; Miss H., Lond.

I.—International News Co., Lond.; Institute of Chemistry, Lond., Secretary of; Ichthyol, Lond.

J.—Sir George Johnson, Lond.; Dr. O. Jennings, Paris; Justitia.

K.—Mr. C. B. Keetley, Lond.; Messrs. Kennedy and Co., Lond.

L.—Dr. B. J. Lee, Lond.; Dr. T. G. Lyon, Lond.; Dr. T. M. Legge, Lond.; Dr. T. Linde, Ross; Dr. J. M. Lawrie, Weymouth; Sir H. Littlejohn, Edinburgh; Mr. B. Lord, Manchester; Mr. H. Lewin, Hanworth.

M.—Dr. S. Martin, Norwich; Dr. J. Moore, Lond.; Mr. J. F. Milner, Godalming; Mr. J. W. MacAlister, Lond.; Mr. W. J. Maurice, Reading; Mr. H. Mapleson, Lond.; Mr. P. Musgrave, Aulus-les-Bains, France; Mr. R. W. Marston, Berne; Mrs. F. Macarty, Kenmare, co. Kerry; Maltine Manufacturing Co., Lond; M.D., Lond.; Mona.

N.—Dr. J. S. M. Nurse, Anguilla, West Indies.

O.—Messrs. Orridge and Co., Lond.; Messrs. O'Driscoll, Lennox and Co., Lond.; Messrs. Oppenheimer, Son & Co., Lond.

P.—Mr. F. Penny, Barnstaple; Mr. Young J. Pentland, Edinburgh; Miss Peck, Sleaford; Messrs. A. and F. Pears, Lond.; Principal, Croydon; Preston, Lond.

R.—Dr. C. Rogozinski, Warsaw; Dr. W. Robertson, Newcastle on-Tyne; Mr. Arthur Roberts, Lond.; Mr. J. D. Rhodes, Lond.; Mr. F. J. Reilly, Lond.; Rusticus, Lond.

S.—Mr. H. Sewill, Lond.; Mr. E. Swindells, Barking; Mr. M. Summers, Southampton; Mr. A. H. Simpson, York; Mr. W. S. Sprent, Slingsby; Mr. F. H. Simmons, Johannesburg; Messrs. Shanks and Co., Lond.; Messrs. Street Bros., Lond.; Messrs. Leathing and Co., Malvern; St. Luke's Hospital, Lond., Secretary of; St. Peter's Hospital for Stone, Lond., Secretary of; Sanitary Institute, Lond.; Surgeon, Burgess Hill; Scalpel, Huddersfield.

T.—Dr. W. Travers, Lond.; Dr. F. M. Turner, Lond.; Mr. J. Thin, Edinburgh; Mr. C. B. Taylor, Nottingham; Mr. A. H. Tubby, Lond.; Terrol Co., Lond.; T. A. L. C., Lond.; Trouville.

U.—University College, Cardiff, Secretary of.

V.—Dr. A. S. Vallack, Lond.; Mr. G. Vickers, Lond.; Volunteer Medical Association, Chairman of; Veritas, Lond.

W.—Dr. R. T. Williamson, Manchester; Mr. S. Walpole, Lond.; Mr. A. B. Worsley, York; Mr. E. Wilson, Exeter; Worshipful Company of Plumbers, Lond.; West Riding, Leeds; W. G. R., Edinburgh.

Y.—Yorkshire College, Leeds, Secretary of.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. A. E. Ash, Criccieth; Dr. E. Anklesaria, Sadra, India; Mr. C. M. Atkinson, Saltburn-by-the-Sea; Mr. R. R. Anderson, Carmarthen; Aberdeen University, Secretary of; Agent, Brighton; Alpha, Lond.; Advertiser, East Ham; Abstainer, Lond.; Ashton, Lond.; A. M. G., Lond.; A., Lond.

B.—Dr. N. Burns, Moffat; Mr. B. Brown, Huddersfield; Mr. R. W. Braithwaite, Rickmansworth; Mr. R. Baker, Lond.; Mr. H. Brice, jun., Exeter; Mr. J. S. Buck, Eaton Socon; Messrs. Burgoyne, Burbidges, and Co., Lond.; Bristol Royal Infirmary, Secretary of; Bradford Infirmary, Secretary of; B. W., Eastbourne; Bank, Lond.

C.—Dr. W. H. Corfield, Lond.; Dr. R. H. Coombs, Bedford; Mr. W. P. Clay, Edinburgh; Mr. H. Cross, Dinton, Aylesbury; Mr. W. Curtis, Dukinfield; Messrs. J. Cleave and Son, Crediton; Messrs. Cassell and Co., Lond.; Messrs. Callard and Co., Lond.; Croft, The, Bournemouth, Proprietress of; Cortex, Lond.; Charles, Lond.; C. W. H., Lond.; Cocain, Lond.; Cœlebs, Lond.

D.—Dr. D. Durran, Thurso, N.B.; Dr. Dewan, Johnstone; Mr. J. T. Davenport, Lond.; Mr. O. J. Davies, Ruardean; Mr. C. S. Davies, Lond.; Durham County Asylum, Clerk of.

E.—E. W. H., Lond.; E. M., Lond.; Elpis, Lond.; E. C. W., Lond.

F.—Flower House, Catford, Secretary of; Dr. F. M., Pattingham.

G.—Mr. W. V. Griffith, Coedpoeth; Mr. J. J. Griffiths, Lond.; Mrs. Gann, Hayling Island; Mr. E. J. Gibbs, Banbury; Messrs. Gilyard Bros., Bradford; Messrs. Gale and Co., Lond.; General Mercantile Finance Co., Manager of; Grove House Private Asylum, All Stretton, Secretary of; G. M. S., Lond.

H.—Dr. J. F. Horne, Barnsley; Mr. W. A. Hardiker, Brymbo; Mr. C. G. Heard, Hunmanby; Mr. J. Heywood, Manchester; Mr. A. W. Harris, Southampton; Mr. W. Humphrys, Limerick; Mr. M. L. Hughes, Altrincham; Mr. A. Harper, Raphoe, co. Donegal; Messrs. Hogg and Son, Lond.; Harvard Co., Lond.; Halifax Infirmary, Treasurer of; Miss H., Lond.; H. A. B., Lond.

J.—Mr. T. S. Jackson, Wilmslow; Mr. T. B. Jacobsen, Sleaford; Junior, Lond.; J. H., Hastings; J. H., Lond.; J., Wrexham.

K.—Dr. H. Kerr, Abergavenny; K, Lond.

L.—Mr. M. Lawrie, Weymouth; Mr. W. Land, Wakefield.

M.—Dr. A. A. Moore, Bedhampton; Mr. J. McMurtrie, Glasgow; Mrs. Medlicott, St. Alban's; Miss May, St. Leonard's; Manchester Royal Infirmary, Secretary of; Mepal, Worthing; M. Y., Lond.; M. A., Lond.; Mater, Lond.; Medicus, Bradford; Dr. M., Southsea; M. A. C., Lond.

P.—Mr. J. Paterson, Lond.; Presbyterian Hospital, Philadelphia, Secretary of; Plymouth Borough Asylum, Ivybridge, Clerk of; Principal, Lond.

Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Latest Therapy of some Animal Substances.

"TABLOIDS" OF THYMUS GLAND.

THYMUS GLAND "Tabloids" represent five grains of the fresh gland substance, and consist chiefly of nuclein and nucleo-albumin. Careful study of the subject has shown that in the human species the Thymus Gland reaches its greatest development under normal conditions about the third year of infantile life, when it begins to atrophy. But in that peculiar pathological condition now known as Paltauf's "Status Thymicus" this organ persists, and its presence may be verified by percussions on the manubrium sternum. It is asserted that the existence of the Thymus Gland in early childhood is compatible with perfect health, but that its persistence into a more mature period—considering the position it occupies between the sternum and the windpipe—renders the patient more liable to asphyxia, from which liability it is inferred, rightly or wrongly, that the Thymus cells are concerned with healthy respiration, by which is meant normal blood oxygenation, and that the ingestion of Thymus substance tends to strengthen the respiratory centres. The renewed interest taken in this gland, and the difficulty which those who wished to give it a trial have experienced in obtaining it, induced us to make arrangements to obtain regular and fresh supplies and to offer it to the medical profession in the "Tabloid" form. It has been suggested that Thymus Gland "Tabloids" may be highly serviceable in many nervous complaints, functional or organic, accompanied by hypertrophy, atrophy, or other interference with the functional activity of the muscular and lymphatic systems—*i.e.*, in pseudo-hypertrophic paralysis, in Basedow's disease with Anæmia, and in all cachectic states in which there may be marked enlargement of the Lymphatic Glands. Possibly Thymus Gland "Tabloids" in association with Medulla (Bone) "Tabloids" would be extremely useful in the treatment of pernicious or simple Anæmia and Leucocythemia. From the fact that before now, physicians, in dieting phthisical and other delicate patients, especially those in greatly emaciated conditions, have frequently found that the Thymus substance rapidly increases the number of leucocytes in the blood, it is fair to assume that these "Tabloids" may be of immense service in the treatment of strumous, scrofulous, and neurotic patients, in cases of rickets, and in the so-called "wasting diseases" of children. "Tabloids" of Thymus Gland supplied to the Medical Profession in bottles of 100 at 2s. each.

Characteristics of the Gland.

The best form of administration.

Therapeutic use and value.

"TABLOIDS" OF THYROID GLAND.

"Tabloids" are far preferable, we are assured, to liquid extracts—especially to such as are intended for use hypodermically, to which method patients usually show a natural repugnance. In a pamphlet dealing with the use of Thyroid Gland "Tabloids," we state, on the authority of a well-known observer, that even so small a dose as the eighth part of a "Tabloid" ($=\frac{1}{11}$ part of an average gland) has been known to produce the most profound reaction. Those who have had the largest experience with the Thyroid Gland as a remedy, whether it be in Myxœdema, Goitre, Exophthalmic Goitre, Cretinism (sporadic or endemic), Psoriasis, Eczema, Lupus, Ichthyosis, or other affections, strongly maintain the necessity of starting with a very small dose—quarter to half a "Tabloid"—at the initial stage in order to test fully the susceptibility of the patient to this treatment, and thus to avoid the profound systemic disturbance likely to occur when too large doses are given. It is also urged as being politic, since the treatment is usually a prolonged one, to administer concurrently a suitable tonic to counteract the debilitating effect likely to be produced. And once the treatment has been commenced there cannot be any doubt that for its systematic continuance and graduation of dose either progressively or decreasingly, and general convenience for self-administration by the patient with the least possible supervision from the medical adviser, "Tabloids" are superior to any liquid form. It is a well known fact that liquid preparations of this and similar structures, putting aside the difficulty of determining definitely their real constitution chemically, are from their very character only too prone to decompose, and the results which might accrue on the administration of resulting ptomaines it would be hazardous to guess. The Thyroid Gland "Tabloids," on the contrary, keep exceedingly well and have stood the test of time and temperature in many parts of the world to their increased reputation; they contain all the active principle or principles to be found in the gland; they are always to be relied upon for uniform activity, because the percentage of active principle must be well averaged, on account of the very large number of glands (brought to a homogeneous mass) dealt with in one operation at our laboratories. "Tabloids" of Thyroid Gland supplied to the Medical Profession in bottles of 100 at 2s. each.

Wide sphere of usefulness.

Liquid preparations unsatisfactory.

"TABLOIDS" OF DIDYMIN.

"Tabloids" of Didymin (Orchitic Substance), already largely prescribed in cases of epilepsy and in various types of hysteria and neurasthenia depending upon functional failures or derangement, have lately acquired a new interest on account of recent records in the medical journals of the successful treatment of various nervous diseases. The cases quoted by an eminent practitioner in the BRITISH MEDICAL JOURNAL of June 8th, 1895, have apparently aroused considerable interest, judging from the many enquiries we have received. Those medical men who have had disappointing results with liquid extracts of Orchitic Substance will do well to renew treatment, if cases are still available, with the same remedy in the form of "Tabloids." The superiority of "Tabloids" over so-called liquid extracts will, we think, be again shown as markedly in the administration of Didymin Substance as it was in the case of Thyroid "Tabloid" medication. Didymin "Tabloids" are supplied to the Medical Profession in bottles of 100 at 1s. 6d. each.

Presidential Address,

Delivered at the Sixty-third Annual Meeting of the British Medical Association, at London, on July 30th, 1895,

BY SIR J. RUSSELL REYNOLDS, BART., M.D.LOND., F.R.C.P., F.R.S.,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION, CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, AND PHYSICIAN IN ORDINARY IN HER MAJESTY'S HOUSEHOLD.

ON THE ORGANISED PROGRESS OF MEDICINE.

GENTLEMEN,—Twenty-two years ago the British Medical Association held its annual meeting in London, and last year the members of the Metropolitan Counties Branch thought there were then abundant reasons why the Association should be invited to assemble here again, and the whole meeting of the Society convened in Bristol cordially accepted the invitation.

The Association was presided over in 1873 by the late Sir William Fergusson, the most distinguished surgeon of that day; there must be hundreds here who remember him well: his grand physique, his skilful and, indeed, artistic performances; the absolute ease with which he bore himself under the most trying circumstances of unavoidable accidents and yet not unforeseen, of events which no human knowledge could forecast, and of difficulties which needed all his resources of hand and courage to encounter. Yet, gentlemen, I venture to say that if, like a well-known but not quite historic character, Sir William Fergusson could have fallen asleep about that time, and have not waked up again until now, and were capable of appearing amongst us again, absolutely unconscious of the kind of progress made in surgery during those two-and-twenty years, and of the steps by which such progress was carried to its successful ends, even that dauntless surgeon might pause to perform an operation which either of his dressers of twenty years ago might be announced to do to-day, and would do without fear or dread. "Experience is by industry achieved and perfected by the swift course of time." Such industry has been unsparing, I may also say relentless, not in consideration of the patient, but of the worker. It has come from all sources of scientific investigation that could be focussed in the operating theatre, and it has done more than the surgeon of my student days—and Robert Liston was daring enough—could have foreseen even in his most optimistic dreams.

The Address in Medicine was delivered in 1873 by the late Edmund Alexander Parkes, and all of us who remember him, and all who have become acquainted with his writings, know how vast was his range of information, how keen his foresight, and how subtle and yet how true his faculty as a critic; but still, if Parkes could, even after only the few years since his untimely death, revisit Netley, or his still older haunt, University College, even he would be entirely bewildered and amazed if he found his house physician feeding a patient on sweetbreads, or injecting thyroid extract for the cure of myxœdema. In physiology, in pathology, and in medicine advances, equally important to each, have been made during the past two-and-twenty years. It is not my intention to occupy your time with any details on these matters; but let me recall for a moment your attention to the vast strides that have been made in the elucidation of both structure and function—such, for example, as in the researches upon the thyroid, the adrenal bodies, the spleen, and the liver; the advance of bacteriology; the function of the axis-cylinder of nerves; and the magnificent prospect before us of a new field of therapeutics in the serum treatment of disease. Physiologists, pathologists, and therapeutists have "seen visions" and in the past have "dreamed dreams"—as we may be dreaming now—but the facts, now well before us, have certainly astonished even the expectant, have surpassed their imaginations, and opened before them, not one only, but many doors into regions crowded to the full with yet more fruitful information, waiting only to be arranged and utilised.

So much of the work that has led to this present state of science has been accomplished in the metropolis that, although we know what has been done and is still being done in the provinces, we thought it well to ask you to meet us here, tell us of your own work, and join with us in a mutual endeavour to gather more and more by combined work and earnest, honest rivalry for truth than we could do by disunited efforts. What my object in this address is mainly concerned with is to draw your attention to that which seems to me to be the most striking fact of modern physiological, pathological, and therapeutical research—namely, the power of "living" things for both good and evil—namely, in the conservation of health and in the prevention or cure of disease. The mineral and inorganic world has helped us much, but now our help and hope come mainly from organised products and still living agencies.

During the last twenty years there has been established, to the great advantage of our profession, the "Conjoint Examination" by the Royal Colleges of Physicians and Surgeons. This, while not interfering with the autonomy of either College, has raised the plane of education required of all who are candidates for entrance into the profession, and has so brought into combined action the Colleges themselves, that they have added, each to the other, authority and dignity in the recommendations they have made from time to time with regard to matters of education, Parliamentary proceedings, State medicine, and scientific research. But the building on the Thames Embankment, which will be well seen during the next few days, is very much more than an Examination Hall: it is the centre of a very hive of industrious work. You will see there the most recondite and obscure processes of Nature under the most elaborate scrutiny and faithful record. The delicate phenomena and suggestions of "living" and "chemic" functions are under minute survey, analysis, and detail. The points where they touch, the mode in which facts of either may be rendered in terms of the other; their bearings upon the life of animals and men, both as individuals and as parts of a community; the diagnosis of the most obscure diseases, and the tentative and more than tentative endeavours to counteract poisons, which can be separated but not destroyed, over-ruled but not abolished,—these, and much more, you will see under the skilful and careful guidance of the able director of the laboratory, who, with his many coadjutors, will gladly welcome all those who are interested in such minute research. This is one of the products of the last twenty years, but it does not stand alone; the Brown Institute, the Society for the Promotion of Knowledge by Research, the laboratory of University College and of the other large schools, are all doing similar work, and constitute the most promising features of the present day with regard to advance in the science and art of medicine. In all our schools you will, I am sure, find very great improvement in the mode and scope of teaching; and this especially in it being less didactic and more practical. Much of the old-fashioned, often dreary "lecture" of an hour's duration has passed away, and in its place is a "demonstration," an "object lesson," a conversation, or examination. These are more useful and therefore more attractive to the students, and at the same time more trying, but none the less efficiently rendered by the teachers. Again, in clinical teaching you will observe much more and closer personal relationships, not only between the physician and student, but between the student and the patient. The latter is not a mere "dummy" in a bed, exhibited as a specimen of this disease or that, but a "human being" to be spoken to and to help you—I mean the student—to find out whether or no the card at the head of his bed, on which the diagnosis of his malady is supposed to be written, is correct or as full as it might be.

Then there is another point which has struck me much during the past ten years, and especially so whenever demonstrations are being given, either at the bedside or in the laboratory, namely, the far greater interest and earnestness which characterise the student of to-day as compared with his predecessor. Much of this is, I think, due to the indulgence of a larger hope. Hidden as still are the great mysteries of life, there yet are definite facts to be grasped by the mind, to be seen and handled, not only imagined or asserted; and the place of these facts in the economy of Nature, their bearing upon others, and their relation to work yet to follow, give a precision and confidence to study that is, comparatively speaking, of modern growth. There was plenty of assertion and show of knowledge in the past; but even the teachers did not believe the half of what they taught, or comprehended the half of their sage pronouncings. Nature has, as it were, taken man more into her confidence, and daily reveals so much, even while concealing more, that the

Digitized by Google

learner stands firmly on the ground he has gained, instead of trembling on a quagmire, the length and breadth and depth of which he could not see and did not care much to imagine or investigate. He felt sure of little then but of his own and his teacher's ignorance, but now he grasps much that is ascertained truth and such as can be seen, shown, measured, and recorded with perfect accuracy. Our metropolitan museums in Bloomsbury, South Kensington, and Lincoln's-inn-fields will afford to all museum lovers an ample reward for careful examination. Two of them were splendid examples twenty years ago of what could be done to make "collections of material" instinct with information and object-lessons of physiological and anatomical lore; but the marvellous accumulations that have reached us during the period I have mentioned are, I think, only exceeded in marvel by the industry, high thought, and consummate skill with which these materials have been arranged, and made to tell, in their own way, the story of their being and of their place in the great Cosmos of which they form a part. The journal of the Association informs us that the work of this meeting will be carried on by fifteen sections, fully equipped with their respective officers, and each presenting subjects for discussion to be brought forward and threshed out by able hands. But let me remind you that these sections, or at least many of them, have had now, for varying numbers of years, their counterparts in the metropolitan and provincial branches and societies, where discussions are taking place all the year round, records of which are constantly published in magazines, proceedings, and other appropriate journals. In this manner the increase of medical literature has become enormous, and as a rule its value is very high. Of course, it would be too much to suppose that, coming from so many sources and from such differently constituted minds, its merit should always be equal or of the highest order. It cannot be expected of all who write and all who speak that one should say, as was well said of one of our late distinguished members, "he spoke because he had something to say, not because he wanted to say something." In the business of these societies it is the bringing together of recent facts or ideas and the friction of mind with mind that is so useful in separating the real and substantial from the imaginary or accidental; and in this work all our large towns and even country districts are assisting; and the marvel is that when we meet, even as we do now here in the metropolis, there should be such a tremendous store of material to be brought before us for discussion or reception. For example, in the Section of Medicine alone there are three subjects for discussion, and on these fifty members have already expressed their wish to speak; there are, moreover, thirty papers promised, and it is to be expected that few of these will pass without any variety of opinion on their merits being entertained and expressed. It is not to be imagined that all that is advanced will be either new or true, but of this we may be sure—that nothing will be brought forward without duly careful consideration, and apart from the belief that it is worthy of the time and the attention which those who are present will be asked to bestow. I am induced to make these remarks by the fact that the number of members of the Association is now three times as great as it was when we last met in London, and it is one of the most important events of the last twenty years that such an organisation should have grown into being, and should have such a vast influence for good over the whole civilised world.

There are some points in our present state of scientific precision in which, to my mind, it would appear we have made but little advance. We know much more about diseases, their origin, their anatomy, pathology, inter-relations, modes of ending, and their treatment; but with regard to nosology and nomenclature there is little of which we have to be proud. Groups of symptoms have been described by different observers as marking some tolerably distinct departures from recognised types of malady, and, for want of any nosological position being assigned to them, they are called after their first describers' names, and so we have not only Bright's disease, Addison's disease, and Graves' disease, but a host of others, often indeterminate in character, going by the name of Friedreich, Raynaud, Hodgkin, and others, until there is a fair prospect of every distinguished pathologist or clinical investigator being handed down to posterity as a disease the name of which conveys no semblance of a meaning as to its nature. Still further, and more to be deplored, there are smaller groups of symptoms which are not honoured by receiving the names of their describers as separate diseases, but the names of the observers are tied on to the symptoms; and so Cheyne-Stokes' breathing, Corrigen's pulse, von Graefe's sign, somebody else's phenomenon, and a multitude of other like phrases are used, to the great confusion of the student, and not only so, but to his real and permanent injury. For what is easier to say than that there is "Cheyne-Stokes' breathing" except to feel a sense of rest in having made use of that learned phrase, and so practically to shut the door to further inquiry as to what it means and how it comes about, what its diagnostic or prognostic value may be, and how it bears on therapeutics? When quite a boy I was watching the dying bed of my maternal grandfather, aged eighty-four, who had been afflicted with right hemiplegia and aphasia a few days previously. Of all medical terms I was absolutely ignorant, but that variety of breathing struck me much—as it was likely to do—and after observing several long pauses I exclaimed to the nurse, when he had not breathed for over a hundred seconds, "Surely he is gone now!" To my surprise the practised old observer replied, as she looked up from her knitting, "Oh, lor', no, sir; they never goes that way!" So far as my own experience teaches me she was right; but I have not yet met with a satisfactory and thoroughly scientific explanation of Cheyne-Stokes' breathing nor of its prognostic value. Of course, to give the proper name to a disease is to place it where it should be nosologically, "at home" and understood; but medicine is not a science yet sufficiently "ordinated" for this thing to be done, and so we grope about and "gather dust and chaff" with little chance or hope of turning them to value; and instead of making this the matter of most serious investigation and finding the true relation between the new "group of symptoms" and those others which form the central facts, the backbone and whole skeleton of pathology, we lay hold of the first piece of red tape ready to our hand, tie up the group of symptoms in a bundle, and label it Brown, Jones, or Robinson's disease.

A suggestion was made not long ago by one of our most able and energetic thinkers that some apparently new diseases might perhaps with advantage be named provisionally after the patients who exhibited them. This certainly had the merit of originality, as it struck me at the time I heard it; but in looking at my case-books I found that already I had several times adopted it, in so far as to say, "Case X Y Z resembling in particular features that of A B C," or some other very familiar patient. But nothing could be worse for scientific medicine than any such retrograde proceeding. If there be any danger of nomenclature resolving itself into a catalogue of the names of distinguished pathologists, as has been suggested, it would be a still more terrible disaster if a differentiation should be carried still further on this dual system of nomenclature, and that the student should have to be examined in his knowledge of the "George Brown variety of Robinson's disease" or the "Max Schott's deviation from von Hopner's sign." At the very time that there is this increasing use of loose phraseology there is also—as is common enough in other departments of life—a marked tendency in the opposite direction, and that is to connote as diseases certain groups of symptoms by some short or long and often not very appropriate word or words, such as acromegaly, hypertrophic pulmonary osteo-arthropathy, appendicitis, pseudo-hypertrophic muscular paralysis, and others. There is abundant precedent for this; some are time-honoured and old enough to be allowed to live, such as pertussis, epilepsy, apoplexy, chorea, gout, and rheumatism, which have the merits of brevity and of meaning; but there have crept into ordinary conversation nowadays a number of expressions which aid us little or, as I think, not at all; and such words as gastrojejunostomy and as laparotomy do little more than lay us open to the satires of the playwrights of the last century in foreign countries and its predecessors in our own.

But whatever may be our failures—and they are small compared with our enormous successes—there is nothing that has happened during the past twenty years to be compared in importance, as I have already said, with the new revelations that have been made of the potency and pre-potency of life—the power of life in life—in health, in disease, and in its treatment. I allude, of course, to the interpretation of much of the functions of certain organs, the existence of which had been known for many years, but the utility of which had been absolutely unknown—for example, the pituitary body, the thyroid gland, the suprarenal capsules, and others.

Digitized by Google

The knowledge of the functions of the liver and the spleen has been gradually increasing for a long time, and only by slow degrees have the metabolic properties of these organs taken the place of the older ideas of secretion of bile and balance of weight. It has been, on the other hand, although the outcome of serious investigation, but also somewhat by a fortuitous concourse of thoughts and events, that the most astounding revelations of modern physiology have been made. What we have come to know amounts to this in general terms—that the absence of certain organs, of the functions of which until quite recently we knew nothing definite, leads to grave and diverse diseases of the body, whether this absence be brought about by surgical operation or by disease more or less individual or specific in its character, and that, such being the case, the supply of the material of that organ as food, or some part of it, as an extract, to be introduced into the blood, removes the symptoms, acts with great promptitude, and, I might say, almost with some violence of disturbance of the whole economy. Not only so, but these extracts seem to possess a power reaching far beyond that which was first found to be their almost anticipated result—that is, in so modifying the action of the heart and the intravascular pressure, in a manner and to a degree entirely unlooked for, and requiring much further investigation, in order to unravel the true nature of the functions of those organs in health, and the value they may have, by their products, on the processes and treatment of disease. As yet we are only on the threshold of still greater discoveries in regard to life, but we see, through the portal, ranges of facts which are trustworthy guides as well as sign-posts, and which will, we believe, lead us to a larger knowledge of those recondite processes of life in its most essential and characteristic features—namely, of the nutrition of all organs, of the way in which this is brought about, and of the inter-dependence of all tissues, so that, perhaps, in a far higher sense than we have ever realised before the truth may be revealed that "when one member suffers all the others suffer with it," and the reason of this may be explained. A very obvious consideration which should "give us pause" in self-congratulation is this, that as in past days the functions of different parts of organs—the kidneys, for example—were more or less clearly separated by physiologists, no longer with us now, so we have seen recently that only certain portions of other organs have the physiological effects just discovered, and thus that there may be in what we have regarded as much simpler organic components, even in quite simple tissues, some unconsidered element of function, some *sine quâ non* of healthy life, some missing link in the phenomena of life, so that it behoves us to keep the mental eyes wide open to clear away all films of prejudice or hasty complacency, to expect the unexpected, and so, without looking for it, to find our reward. Not less important than the matter I have just referred to is the recent development in "microbiology" and "all that therein is." The "germ theory" of the disease is not new. When it commenced and who has the credit of its begetting I do not know. Probably, like ancient and modern heroes, it had many parents and as many homesteads. It is quite clear that our own great Harvey entertained it, as may be seen by the following: "Let physicians cease to wonder [he says] at the manner in which epidemic, contagious, and pestilential diseases scatter their seeds and are propagated to a distance through the air or by some 'fomes' producing diseases like themselves in bodies of a different nature, and in a hidden fashion silently multiplying themselves by a kind of generation until they become so fatal, and, with the permission of the Deity, spread destruction far and wide among man and beast, since they will find far greater wonders than these taking place daily in the generation of animals." Years later it was a hobby ridden by many, but without much convincing proof. But even so late as 1866 we find that advanced pathologist, Dr. Edmund Alexander Parkes, saying, with regard to the etiology of influenza: "We find ourselves in the presence of the so-called fungoid theory of influenza," and, after discussing this matter at length: "It seems impossible at present to come to any conclusion as to the nature of the cause."

The most important fact with regard to recent microbiological research is the gradually increasing appreciation of the fact that these lower forms of life exert, not necessarily mischievous, but indeed benignant influences on the human body, and that although the mode of their operation is not fully explained they take part in healthy processes, assisting normal functions—nay, indeed, it would seem sometimes producing them and warding off the malign effects of other influences to which we are habitually exposed. These bodies, to which we are indebted for this aid, operate partly by their chemic action and partly by what we must call a vital process, and by their cultivation outside the human body and their modification by passing through other organisms can be made to exert a malign or a beneficial agency on man. It seems even in the range of possibility that at some time not very distant some other than "the ancient mariner" may apply to them the far-reaching words of Coleridge and exclaim:—

> "O happy living things! no tongue
> Their beauty might declare;
>
> Sure my kind saint took pity on me,
> And I blessed them unaware."

The third great revelation of the last twenty years is the wonderful protective and curative power of these living products. This, in a very wide sense, is not new. Of all the most powerful agents of destruction the most violent have been derived from "living" things; they are to be found in the animal and vegetable worlds, not in the mineral. In their most terrible malignity—such as in snake-bite, glanders, or hydrophobia—these need no human skill for their development; they are prepared in the laboratory of Nature, and, alas, are only too ready to our hand. Next to these come the poisons of stinging things, and after them the more slowly operating and less deadly animal infections; some with indeed beneficial influence, as "vaccinia"; others with local effects on the skin, but not often great disturbance of the general health. The vegetable kingdom can produce potent poisons, such as belladonna berries, aconite root and leaves, poppy juice, and the ignatian bean; but in order to render these more deadly the hand of man has to come in and prepare nicotine, strychnine, morphine, and the like, just as it may produce, from the mineral or quasi-mineral world, such potent agents as hydrocyanic acid, concentrated acids, and other dealers of destruction. The interest in these facts lies in the modern mode for their utilisattion. The great potency of living products has led to very fanciful notions in therapeutics; and there have been those who, to cure diseases of organs, have given portions of the same but healthy organs of animals or of man or other animals. Again, the idea has been pronounced that even excreta were useful drugs, and that the diseased organs of man might effect a cure of those supposed to be afflicted in like manner. Curious as some of these details are, they are of real interest to us only as they lead up, through inoculation for small-pox, to our own Edward Jenner's discovery of vaccination, and then, through the researches of Pasteur and Brown-Séquard, to our present state and plane of knowledge. It would seem now that there is scarcely any limit to what may be expected in the cure or prevention of disease; and the most striking of all phenomena is, to my mind, the probability of rendering an animal immune by the introduction into its organism of a healthy constituent of the body of another. This, if fully confirmed, will be the greatest veritable triumph of therapeutic and preventive medicine, instituted and guided by extended inquiry into comparative anatomy, physiology, and pathology. As in the human race or species there exist, as is well known, what may be termed "idiosynerasies"—by which is simply meant that as a matter of fact some people, and some people's families, escape epidemic diseases, whereas they are especially prone to take others to which they may be exposed—so in the great economy of nature certain groups of animals have been shown to exhibit no capacity for "taking," or for even being "inoculated" with the poisons to which others are exposed, and from which they suffer, and that severely. It would seem, therefore, that use may be made of these animals more or less naturally immune from certain maladies, and that their immunity may be partially conferred on man. Quite recently a communication of the greatest importance has been made on the rendering of animals immune against the venom of the cobra and other snakes, and on the antidotal properties of blood serum of immunised animals. This subject has occupied attention during the last six years, and we must all look forward with expectancy and hope to the possible and probable diminution of a great national and imperial calamity.

The outcome of all that I have been saying is this: that the scattered fragments of knowledge and "guesses at truth" of many years have been gathered into a focus during the past twenty-five years; that the vegetable life, extracting

Digitized by Google

from the mineral world the materials it needs for growth and production of powerful agencies for good in the form of food and medicines, and for evil in the form of poisons, has given itself up to the growth of animal life, with its much more complex organs, and for the cure of ills once thought beyond the reach of human aid; but that, thanks to man's scientific ardour and industry, it has again shown itself to be our servant, our helper, and our protector. These are not dreams of the study, they are facts of the laboratory and of daily life; and in using that word "life" again I must endeavour to emphasise still more forcibly upon you my urgent belief that it is to living agencies and their employment that we must look for help in the care of infancy, the conduct of education—moral, mental, and physical—the training up of character as well as of limbs. That it is the guidance of living functions, in the choice of living occupations, be they either of hard work or of amusement; it is to these we must appeal if we would see the *mens sana in corpore sano;* and then it will be to these that we may confidently look for help when the inroads of age or of disease are at hand often to cure us of our trouble; or, if not, to give us rest and peace. It would be absurd in me, now and here, to attempt to say in what this potency of life exists. It is enough for us to recognise its existence, rejoice in its marvellous energy, and anticipate still more from our investigations of its modes of action; but I cannot help feeling that, however far we go in our research into the arcana of nature, one of our ablest neurologists, who has gone very far, is right when he says: "Search while you may, with eyes, however aided and however earnest, that which we call 'life' eludes our search and resists our efforts. We must be content with what knowledge we can gain, secure or insecure, and while using it as best we may, should realise in all humility how much there is we cannot know, and yet we cannot doubt."

There are three aspects of life to which I wish to make further reference, because it seems to me very important that this Association should at some of its annual meetings direct special attention to their consideration. And first a few words on "professional" life. As physicians and surgeons, however numerous, we do not constitute a "body" of men unless we have some one prevailing spirit common to us all. The profession may include its thousands and tens of thousands, but it is a crowd, a multitude, or shall I say a "mob," unless there is in it an *esprit de corps;* and, thanks to our great seats of learning, our universities and colleges, we have developed this uniting spirit now for many years. But our own special colleges of physicians and surgeons, our medical societies, and especially this vast Association, have done more within the last fifty years to give real, unifying life to its individual members than was possible, or even expected to be possible, by our forefathers. There are sixty branch associations in direct communication with our colossal trunk, spreading themselves not only over the United Kingdom, but to the remotest parts of our dominions; and these are all equipped with efficient officers, holding meetings all over the world, discussing the really important topics of the day, and adding their contributions to the sum of knowledge through the pages of our quite remarkable journal. Now this is very encouraging and very hopeful, but it entails, as it is bound to do, great responsibilities. That so large a body of men should be banded together under one common name means that they have some common purpose, and some common plan of coöperation to attain it. What that purpose is we know—namely, to render our profession of the highest service, not only to the individual, but to the State, by taking our share and giving our advice in the making of our laws, so far as they affect us, as members of our profession; by the regulation of our charities, the guidance and control of labour, the care of the pauper and the pauper child, the lunatic and the quasi-lunatic, or the habitual drunkard; by the care of our poorer brethren; by the advance of scientific researches, and especially of those that require combined efforts and combined funds for their prosecution; by the promotion of useful and stable literature; and by the elevation of all that constitutes the education of the man of science, the physician, the surgeon, or the guardian of the public health. These noble purposes cannot be achieved, nor have any of them been carried to any useful extent, without self-sacrifice, as well as the sacrifice of time, without a consideration of the views of others as well as an assertion of one's own; without respectful regard to the feelings and positions of our colleagues, as well as a due estimation of those which we may occupy; without patience as well as work; and an all-pervading sense of hope in the midst of trying times and in the darkest hours. One thing, in addition, we should all most strenuously try to do, and that is to avoid waste of time. We may use it or sacrifice it freely, but we cannot afford to throw away one moment, whether it be on personal ends, forlorn hopes, foregone conclusions, or threshed-out heaps of seedless faggots. It is in this spirit, I am sure, that we begin our vast meeting in the metropolis, and if we but continue along the lines of conduct our Association dictates, and if in the control of the affairs of our daily life we always bear in mind our belonging to a noble profession, and to a great Association of fellow-workers for its benefit and for the benefit of mankind at large, we may hope to see that—useful as it may be now—at some future assembly of our fellows it will not be found necessary to constitute a special section for the discussion of those questions which fall under the category of ethics.

Outside our professional life, but closely mixed with our daily work, is the "social" constitution, or, as some would call it, the "environment" in which we have "to live and move and have our being." Certainly it has changed much within the last twenty years, and it would be impossible for me to dissect it now and say in what ways we have advanced and in what others we have either retrograded or gone far, far out of the beaten track. The changes on all hands are pressing, importunate, and, I might say, overbearing. They are not seen in the assemblies of such reverend bodies as the Royal Society, the Colleges of Physicians or Surgeons, or in the higher courts of our universities, but may be met with in the courts of law, the park, the theatre, the concert room, the school, the public assembly, the drawing-room, and, last, and worst of all, in the home. It would seem as if "reverence, that angel of the world," had from some regions taken flight, and that in her place were idols, or mocking shadows, or gorgeously appareled lay figures. This absence of reverence shows itself everywhere, but perhaps it is possible to classify even such a negative quality and put its leading features under three great categories: (*a*) reverence for all that constitutes the religious element in life; (*b*) for that which is the groundwork of "social" propriety, and I may say even of decency, as our predecessors would have thought; and (*c*) for the constituted order of relative dignity in "family" life. Thus, much that now passes for wit, humour, cleverness, or fine and advanced thought may be easily resolved into offences either against the religious sense of others—that is, trespasses in the direction of profanity—or against the long recognised standards of propriety, in topics of conversation, in literature and art; or sins in many directions against the widest meaning of the old commandment, "Honour thy father and thy mother." If all shades of profanity, impropriety, or rudeness were eliminated from what now passes current in books, in plays, and in conversation, we should, I think, often find little or no humour left, but only a vapid attempt at seeming cleverness, or at best some silly pun. Even the epigrammatic style of writing and talking at which there is so much attempt, especially in the conversations detailed in the modern novel, has generally lost all real point and excellence, and in most instances has degenerated into clumsy efforts to be smart and unintelligible or to gild the refined gold of the setting of that priceless gem of humour when natural and spontaneous, the true "Irish bull." The sparkle of the humour is lost, there is a semblance of a paradox, and wrapped up in this an obvious and often intentional untruth. If this were rare we could let it alone, least of all could we think it worthy of notice in the meeting of this Association; but it is not rare—our literature is positively flooded with this senseless and misguiding nonsense, even science is sometimes dragged into its degrading service, and the profession of medicine has not escaped its touch. If we ask ourselves, "What is the meaning of this and whence its origin?" I do not think we shall have very far to travel. Of late years there has been imported into our country a phrase which, in my humble opinion, is abominable in itself and in its power for evil. I will not quote it; but let me ask you if you do not think that this idea of the approximation of the "end of the nineteenth century," with the nonsense that has passed into its literature, has not had much to do with it? It may be that the notion has arisen in some minds that when its "crack of doom" has come, and they wake into a new epoch, follies will be left behind, no more records will have to be made or broken, wild oats will be trampled under foot, and no more will be sown; that there will be an end to the

Digitized by Google

frivolous talk of the last decade, that a "new earth" will be here for us to tread, and that if there be any idea of a heaven lurking in such minds, there will be a "new heaven" also. It has seemed to me that something like these notions have passed current in many circles, and have been held to excuse what would otherwise be not only inexcusable but intolerable.

Now, gentlemen, it is against all this absolutely unscientific and unphilosophical verbiage that, I think, we, as members of the profession of medicine, should utter our strongest protest. Nature does not progress by leaps; the terms, limits, and boundaries of time are convenient arrangements we have made for ourselves; to pass them may make or destroy some legal powers or exemptions from responsibility; but they have, in themselves, nothing whatever to do with the essentials of our individual and domestic life. When the last stroke of the bell has knelled in the midnight of London the last hour of 1899, do we really think that either here or there or anywhere it will carry with it any substantial meaning or any wholesome lesson? I cannot for a moment believe it will. Old and young people will die in the awakening as in the dying year; babes will be born in the one century and in the next; there will be bridal feasts and funeral marches; wisdom and folly; sickening accidents and more sickening crimes; there will be "new women" and "new men"; but there will also be "old women"—and those of both sexes—and "old men" to tell us of the far better days when they were young and everyone was wise. As physicians and surgeons we can, I think, do much to counteract this, as it seems to me, growing tendency of the present day. In the nursery, in the schoolroom, and yet a little later we would give advice, and that of useful sort. Little girls and little boys may strip themselves as high as may be, and paddle on the sands of the salt sea shore with relative impunity, for they rarely venture into water over ankle-deep; but when a few more years have passed, and, exposed as society now sanctions, they roam on another shore of that "Ocean of Time whose waves are years, treacherous in calm and terrible in storm," they may be overtaken by the tide they have courted, and to them "Life be never the same again." There is still the one great and greatest relationship of life to which I will address myself, but only for a brief period—I mean the conduct of our profession to the "religious" element in our nature. Here we have nothing whatever to do with creeds, be they hoary with age or flushed with the bloom of youth; all that I mean is that we, members of the medical profession, have to deal with those to whom these creeds mean much, and are, with what they entail to many, the be-all and end-all of existence. I am not thinking for a moment of the few substitutes proposed for religious faith, but referring only to that which relates those who entertain it to the Higher Power, the source of Revelation and of good and hope, far other than is to be found in themselves or in Humanity, be it in the Future or the Past. I am sure that in giving the help we hope and ought to give to suffering and sorrowing man we shall do nothing worthy of the name unless we realise, and that to the full, the importance of this factor in our lives and theirs; and so guide its operation as to help it to chasten, subdue, control and comfort those to whom it is the minister that they feel to be sent from God to help them in their passage through this region of passing shadows to that of realities which are abiding things.

Acting in this spirit in our professional life, and in our relation to the social and religious lives of our friends and patients, we may, I think, take courage, and, entertaining a larger hope from holding a larger view of life, adopt the words of the Laureate of the first half of this century and exclaim:

> "Look forth, my soul!
> (Nor in this vision be thou slow to trust)
> The living waters, less and less by guilt
> Stained and polluted, brighten as they roll,
> Till they have reached the eternal city, built
> For the perfected spirits of the just!"

PRESENTATION.—Dr. Francis Wm. Clark of Lowestoft has been presented with a testimonial from the St. Margaret Lodge of Ancient Free and Accepted Masons, No. 1482, Grand Lodge of England, on the occasion of his leaving Lowestoft for Hong Kong, which consisted of an artistically illuminated address, expressing the cordial appreciation, by the Worshipful Master, Past Masters, Officers, and Brethren, of Dr. Clark's valuable services during his membership of the Lodge.

Address in Medicine.

Delivered at the Annual Meeting of the British Medical Association at London, July 31st, 1895,

BY SIR WILLIAM BROADBENT, BART., M.D., F.R.C.P. LOND.,

PHYSICIAN TO AND LECTURER ON CLINICAL MEDICINE AT ST. MARY'S HOSPITAL, AND PHYSICIAN IN ORDINARY TO H.R.H. THE PRINCE OF WALES.

THE GROWTH OF THE ART AND SCIENCE OF MEDICINE.

MR. PRESIDENT AND GENTLEMEN,—The heavy responsibility of delivering the Address in Medicine on the occasion of the visit of the British Medical Association to London has been placed upon me by the Council of the Association. The opportunity of addressing so many colleagues as are assembled here rarely happens to a medical man. The honour attending it is very great, and nothing short of his best thought and endeavour ought to satisfy his sense of what is due to the occasion. It was under the influence of this feeling that I entered upon the difficult task of deciding what I should bring before you to-day, and it seemed to me that it was better that I should resist the temptation to take up some special subject or a topic of local or temporary interest, and once more go back to the past and see what lessons it has for us at the present day. I propose, therefore, to consider the growth of the art and science of medicine. I place the words art and science in this order advisedly, for the art of healing is one of the primary needs of social organisation, however rudimentary, and preceded by many ages the development of anything which could be called a science of medicine. So far, moreover, the art of healing has always been in advance of science, firmer in its basis and more secure in its principles, and even when medicine as a science has realised our highest aspirations the end and aim will be art—that is, skill in the recognition and treatment of disease. At the same time, it is true that until science began to throw light on its path the art of healing struggled blindly on its way, and its advances were intermittent and slow, with long intervals in which there were stagnation and retrogression. All true progress in medicine has consisted in the application of the results of scientific investigation to the facts of observation.[1]

At whatever period of the world's history and at whatever stage of civilisation we may contemplate the physician engaged in combating disease, there will be recognisable three distinct factors in his work—his power of identifying disease, the remedies at his command, and the ideas by which he is guided in the employment of these remedies. The first rough and imperfect identification of the more conspicuous forms of disease was scarcely worthy of the name of diagnosis. Anatomy, which is essential to the localisation of morbid conditions, was scarcely known; no shadow of comprehension of physiological or pathological processes entered into the conception—it was simply the attaching of a name to an assemblage of symptoms, the course of which, however,

[1] In my first sketch of this address I was tempted to use that comfort-word evolution, but I found this term appropriated on every side, and employed to connote such a variety of modes of progress that my poor effort would have been lost in the crowd. Besides, a very little reflection showed me that no such process as "progress from the general to the special," which is what is really implied by the term evolution, can be traced in the history of medicine, but that, as Mr. Balfour says: "Assuming, as we do, that knowledge exists, we can hardly do otherwise than make the further assumption that it has grown, and must yet further grow. In what manner, then, has that growth been accomplished? What are the external signs of its successive stages, the marks of its gradual evolution? One at least must strike all who have surveyed, even with a careless eye, the course of human speculation: I mean the recurring processes by which the explanations or explanatory formulæ, in terms of which mankind endeavours to comprehend the universe, are formed, are shattered, and then in new shape are formed again. It is not, as we sometimes represent it, by the steady addition of tree to tree that the fabric of knowledge uprises from its foundations. It is not by mere accumulation of material, nor even by a plant-like development, that our beliefs grow less inadequate to the truths which they strive to represent. Rather are we like one who is perpetually engaged in altering some ancient dwelling in order to satisfy newborn needs. The ground plan of it is being perpetually modified. We build here, we pull down there. One part is kept in repair, another part is suffered to decay; and even those portions of the structure which may in themselves appear to be quite unchanged stand in such new relations to the rest and are put to such different uses that they would scarce be recognised by their original design."

Digitized by Google

was watched with great sagacity. How remedies were first discovered and how the properties and uses of so many of them as were handed down from remote antiquity were known is matter for amazement. Animals are credited with instincts which direct them to the consumption of certain herbs or mineral substances when their health is deranged; the instincts of the primitive man also must have applied to remedies as well as to food, and experience of their effects must have been accumulated and transmitted, embodied frequently in legend or superstition, as part of tribal knowledge. Of the infancy of medicine properly speaking we know nothing. Individual acts of healing are related in the Old Testament, and the treatment of wounds is described by Homer; the Chinese from remote antiquity had a system of medicine, and medicine has a place in the Vedas; but in the works of Hippocrates, the earliest medical literature which has come down to us, we are at once introduced to the theory and practice of the art of healing at a considerably advanced stage of development. Already there were rival schools of thought and treatment, and disease was discussed with extraordinary acumen from opposite points of view both as regarded its nature and phenomena. Bleeding was in everyday use, not by any means as a routine fashion, but with judgment; cupping also was practised. The virtues of opium were known, and purgatives of various kinds, chiefly irritating and violent, and emetics were familiar remedies; enemata and suppositories and pessaries were employed, and fomentations and poultices in great variety were applied. Hippocrates, whose writings embody all our knowledge of ancient medicine, was born about 460 B.C. He was a contemporary of Socrates, Euripides, and Aristophanes, and was a worthy representative of medicine at that brilliant period of Greek literature and intellect called the age of Pericles. It is true that his knowledge of anatomy was rudimentary, and that his physiological ideas were totally wrong, but he has left of himself the picture of a sagacious observer and wise physician. He was the inheritor of the knowledge and traditions of the school of Cos, and another source of information by which he had profited was the training establishments of athletes, where the influence of diet, gymnastics, and baths on health and vigour was carefully watched. His attitude of mind was towards the study of disease as such, rather than the differentiation of distinct diseases. Refinement in this latter direction had obviously been carried much too far by the school of Cnidos, which he criticised and opposed, where symptoms were looked upon as separate morbid entities. His distinguishing merit, however, was that he was guided by observation and not by theory. Hippocrates could not, any more than his contemporaries or successors, or than we ourselves, escape the dominion of theory; but his theories were generalisations from observed facts, and not deductions from preconceived ideas or so-called first principles. The doctrine with which his name is associated, that of the coction of humours and of critical days, for example, is essentially a generalisation from the natural history of certain simple diseases. In coryza or bronchial catarrh there is a watery acrid running from the nose, or scanty viscid expectoration with obvious constitutional disturbance. A change in the character of the secretion is attended with a remission in the symptoms, and after the discharge of more or less muco-purulent matter there is a return to normal conditions. Something of a like kind is observed in the urine in fever and in the stools in diarrhœa. For the accomplishment of these changes a certain time is required, which, when ascertained in each class of disease by careful observation, gives the critical day. The facts were essentially facts of the natural history of disease. The theory evolved as an explanation of the course of events, and applied in the elucidation of disease of which the processes were not patent on the surface, was that some one of the four humours, the due balance of which constituted health, had obtained predominance and set up disturbance, general or local; this was contracted, elaborated by the animal heat, increased for the purpose, and qualified by admixture of other humours, and so brought into a condition in which it could be expelled and got rid of. Hippocrates, from this subordination of theory to observation, from his careful study of the causation of disease, not less than from the lofty sentiments and clear judgments contained in his writings, remains, and must ever remain, the model physician.

During the 500 years which separated Galen from Hippocrates the centre of gravity of the civilised world had shifted. Greece, shattered by conflict between its different States, had succumbed to Macedonia. Alexander had conquered Asia and then died. On the ruins of his empire Rome had gradually risen and when Galen lived had extended her rule over Greece, Asia Minor, Egypt, and the southern littoral of the Mediterranean as well as over Gaul, Spain, and Britain. There had been time, however, for the development of a high degree of intellectual activity and literary culture under the Ptolemies in Egypt, and Alexandria had become a great centre of learning. Here marked advances were made in anatomy, and dissection was practised on human bodies as well as on animals. Herophilus between 305 and 280 B.C. left his name to the confluence of the sinuses of the dura mater; Erasistratus, a contemporary, recognised in a crude way the motor and sensory functions of the nerves; Chrysermes, 240 B.C., writes on the pulse, as does also Heraclides, 230 B.C. Medical writings date from Alexandria as late as 170 A.D., but the school had long lost its authority, and Rome henceforth attracts the highest medical talent. The physicians who first made a name in Rome are Greeks—Asclepiades, the friend of Cicero, and Galen himself. Celsus, however, who comes between the two, writes in Latin. Galen, who was born at Pergamos A.D. 130, as is known to all of you, dominated medical thought for 1500 years, and if it was inevitable that authority should exercise such undisputed sway for so long a period it was perhaps fortunate that it derived from Galen. He was in spirit a follower of Hippocrates and the basis of his ideas on disease and its treatment was observation. His keen and active intellect and fertile imagination, it is true, led him to theorise on every conceivable subject; but the impression left as to his character by reading his numerous works is that of an acute observer, of remarkable ingenuity and profound judgment and excellent common sense. He dissected diligently and thoroughly, but mainly monkeys rather than the human subject. Taking this into consideration, his writings on anatomy were wonderfully complete and exact. They held sway till the time of Vesalius. He finds the most ingenious reasons, often far-fetched and preposterous, for the form, consistence, and relations of all the various organs. In respect of anatomy his knowledge was incomparably superior to that of Hippocrates. He experimented on the spinal cord and on the nerves, and knew that they subserved motion and sensation—knew even that there were motor and sensory nerves distributed to the muscles and skin respectively, discovered the part taken by the recurrent laryngeal nerve in phonation, and, although his physiology is chiefly represented by fanciful teleological explanations of the uses of the different parts and organs, he made noteworthy additions to the knowledge of functions. Apparently Galen was the first to establish the fact that the kidneys secreted the urine, and that it was conveyed by the ureters to the bladder. At any rate this was disputed in his time, the objection being that the urine could not be forced back through the ureters, and could not, therefore, have entered by these canals. The bladder was supposed to attract the urine. He demonstrated it by tying the ureters; and in the course of his experiment he almost stumbles on the discovery of the circulation, for he maintains that blood is carried by the renal arteries to the kidneys in order that its watery part may be filtered off. The traditional ideas of the origin of the veins and of the flux and reflux of the blood in them, however, blinded him to this and other evidence, and he believed that the arteries contained air, though he maintained that they also contained blood. A frequent reproach brought against Galen is that he spoke of the interventricular septum as perforated, so as to allow the passage of air between the two ventricles, against the evidence of his senses; but an excuse can be found for him in the fact that invisible communications had always been supposed to exist between the trachea and the arteries by which air passed from one to the other. He can only have meant similar invisible perforations, the orifices of which he would think he saw in the depressions which the walls of the ventricles present. To convey even the faintest idea of the additions which Galen made to medical knowledge would require more than all the time at my disposal for this address. He wrote more than a hundred treatises on various subjects, including six on the pulse, and, while giving extravagant descriptions and making fanciful comparisons, he pointed out distinctions and characters which have been verified by the sphygmograph. His treatise on local affections is remarkably true to nature, and no more impressive lesson on the value of observation, even when unaided by science and experiment, can be afforded than by realising how fresh and vivid and modern his descriptions of diseases

Digitized by Google

and symptoms sound. His diagnosis, for example, between hæmatemesis and hæmoptysis and other forms and causes of blood-spitting leaves little to be desired. I cannot deny myself the pleasure of quoting a passage which illustrates his robust common sense. He is distinguishing between the different causes of ischuria:—"Suppose the patient to be a child who has previously presented symptoms of stone, watery urine charged with sandy deposits, the child continually squeezing the penis, which is flaccid or unaccountably erect; then sudden stoppage of urine takes place. It may be reasonably concluded that the stone is lodged in the neck of the bladder. Place the child on his back, the hips a good deal raised above the rest of the body; then shake him in different ways so as to make the stone fall out of the canal. After these proceedings tell the child to try and pass his urine. If the attempt is successful and the urine flows you will be satisfied that you possess the exact diagnosis of the cause, and that at the same time you have found the proper treatment. Should the retention persist you will shake him again still more forcibly; if after this it still persist, then with the catheter you will push the stone from the neck of the bladder to reopen a passage for the urine." It might be my surgical colleague, Mr. Jonathan Hutchinson, who was speaking.

The doctrine specially associated with the name of Galen is the humoral pathology accepted by him from Hippocrates and developed. The humours are phlegm, blood, yellow bile, and black bile; and all diseases arise either from a change in the quality of these humours, or from a predominance of one or other of them, or a flux of some particular humour to a given part. But, like Hippocrates, Galen is first of all an observer, and his theories, faulty as they may be, are generalisations from observations and not deductions from *à priori* assumptions as to the nature of things. Both Hippocrates and Galen rejected the doctrine of the sect of empirics, who declared that experience alone, without reasoning as to the nature of relations of observed phenomena, and without reference to causation or to the influence of climate, season, age, sex, character of constitution, or mode of life, was the only safe guide in the treatment of disease. Hippocrates still more emphatically rejected the pseudo-philosophical deduction of rules of treatment from the abstract qualities, hot and cold, dry and moist, acrid and sweet; and Galen in his turn rebutted the methodic doctrine of Asclepiades and Themison which he found prevailing in Rome, according to which all diseases were referred to constriction and relaxation and treatment consisted in relaxing and astringing.

[Sir William Broadbent referred to various Roman physicians living during the Western Empire. He mentioned the early Italian universities, together with the Arabian and Byzantine medical schools. He then passed in review the Middle Ages and the sixteenth century and continued:]

If we take Sydenham, who wrote between 1666 and 1680, and Boerhaave (1668–1738), the best and most representative physicians of their respective times, we find that while they have fully realised the fact of the circulation of the blood it had exercised remarkably little influence on the theoretical views which they entertained with regard to disease or on their practice. Sydenham may be called the English Hippocrates. He was the last and the best of the pure Hippocratic school, unless, indeed, we include Trousseau. He was above all a careful clinical observer. If time had permitted it would have been interesting to compare his knowledge of disease, the remedies he employed, and the theories he entertained as to the causation, nature, and treatment of disease with those of Hippocrates and Galen, on the one hand, and with those of the present day on the other. With regard to remedies the great acquisition of Sydenham's time was bark, which had been brought over from America by Jesuit missionaries about the middle of the seventeenth century. After accepting it cautiously, he employed it freely but judiciously, laying down rules which have been found useful ever since. Mercury was of course in common use, and antimony was an acquisition of which he thought highly. Epidemics he attributed to influences emanating from the earth, and he considered that different years and the various seasons impressed different characters upon the prevalent diseases, in which, in fact, he followed Hippocrates. Other diseases were due to vitiation of the blood; Nature was engaged in the expulsion of the peccant substances. It was the business of the physician to coöperate with Nature, and his art consisted in recognising the indications presented by the symptoms and the direction in which he must act in order to aid in restoring the normal equilibrium. "As for the physician," he says, "all his philosophy consists in following the history of diseases and in knowing how to employ the remedies which experience has shown to be the most efficacious for their cure, and at the same time he ought to follow a method which is founded, not on chimerical speculations, but on a common and natural way of reasoning." Again: "They deceive themselves grossly who imagine that the principal defect of medicine is that it lacks powerful and efficacious remedies which chemistry alone can furnish. On the contrary, what is most wanting to medicine is not to know the means of fulfilling such and such an indication, but to know precisely what the indication is which has to be met. The smallest apothecary's apprentice will tell me in five minutes the drugs I must employ to vomit or purge, to sweat or cool a patient; instead of which to learn with equal certainty when and in what case I ought to employ such and such a remedy in different diseases requires one to be extremely well versed in the practice of medicine." Boerhaave, whose principal works date from the first years of the eighteenth century, was also a great physician, and exercises, by his writings and through his enthusiastic follower and commentator, Van Swieten, a powerful and lasting influence on medical thought in his day. He evidently had great experience and was successful in practice. He had the great merit, too, of teaching at the bedside. He seems to have thought that with the discovery of the circulation and the advance in botany, chemistry, physics, mechanics, and clinical experience, medicine had in his day attained to certainty and almost perfection, but his theories were drawn largely from the assumptions and imaginations of the iatro-mechanical school.

Nothing could more confirm us in our respect for the genius of Hippocrates and the good sense of Galen than to attempt to follow the fanciful extravagancies which from time to time partially displaced their humoral pathology and have been known as the iatro-chemical and iatro-mathematical or mechanical theories. Every discovery in alchemy, as early attempts at chemistry were called, and every new development of mathematical or mechanical science, was in turn seized upon as affording the clue to the causation and treatment of disease. Even the circulation of the blood and the early knowledge of structural anatomy were turned to perverse theoretical use. Just as for the methodics in the time of Galen every disease was referred to constriction or relaxation of parts, and the remedy sought in relaxants or astringents, so at one time all diseases were ascribed to acidity or alkalinity of the humours or to fermentations; or again to obstruction of pores or minute vessels and inspissation of liquids. The contraction of muscles was due to a sudden swelling of their substance set up by the nervous juice or spirits conveyed by the nerves. Respiration was for the purpose of giving a due comminution to the blood by the movements of the lungs. Fever was explained by an acrid nervous juice, which excited the heart to more frequent and forcible action. Later still the physiological discoveries of Haller, the establishment of the principle of irritability as a property of living tissues, and the employment of the term stimulus led to another general theory of disease—the doctrine that fever and inflammation were the result of over-stimulation, which was attended by a return to extravagant and indiscriminate bleeding. From this there was the Brownonian reaction to the contra-stimulant doctrine, with equally indiscriminate, if not equally mischievous, administration of stimulants. Even the revelations of morbid anatomy and pathology were at first made the basis of a general doctrine relating to disease—the organicism of Broussais; everything was referred to gastro-intestinal inflammation, and again venesection was the universal remedy. From this time the character of the work which I have set before myself changes. Up to the present we have only been able to register accretions of knowledge and follow interpretations more or less close to the truth which were advanced in the absence of science. We have now reached a point at which we were entitled to say that ultimately science is to be our guide. Therapeutics will be scientific in proportion as the operation of remedies is referred to physiological laws. Physiology, in turn, is scientific in proportion as vital actions and processes are referred to physical and chemical laws. What remains for us to do is to follow the rapidly converging lines by which this consummation is being approached. Taking up our parable again at Harvey's great discovery, we find that it remained comparatively barren until it was supplemented by Lavoisier's explanation of the process of respiration, and, indeed, almost until a further impulse was given to thought and experiment by a diagnosis of diseases of the

Digitized by Google

heart by means of physical signs. Then an important step was made in the elucidation of the mechanism of the circulation by the discovery of the vasomotor nerves, and the demonstration of the contraction and dilatation of the arterioles in obedience to stimulation of these nerves, by Claude Bernard. Almost concurrently the regulatory apparatus of the heart's action through the vagus and sympathetic was identified by the brothers Weber. These discoveries were followed out in detail by a multitude of experimenters, and the adjustment of the supply of blood to local demands for the purposes of nutrition, secretion, muscular action, and the response of the heart to the general requirements of the system, to excitement, emotion, exercise, are now thoroughly understood. It is only comparatively recently that the blood-pressure in the arteries and veins, and in different parts of the arterial and venous system, first measured tentatively by Stephen Hales, has been experimentally investigated by the graphic method by Ludwig and his school and made available for clinical work through the sphygmograph by Marey and his followers.

The relative share of the heart and vessels in the production of variations in the blood-pressure was thus made clear, and then for the first time the complex and multitudinous indications afforded by the pulse could be understood. At the same time that the lacteals and lymphatics were discovered the structure of the glands was investigated by Glisson and Wharton, and the study of minute anatomy of the tissues generally was initiated by Malpighi, Ruysch, and Leeuvenhoeck, who demonstrated the capillaries by injection and recognised the corpuscular elements of the blood by means of the first rude form of microscope. The invention of the microscope opened another avenue to knowledge, and every improvement in this instrument and in the preparation of structures for examination has been followed by a further penetration into the secrets of organisation and a better comprehension of function. Staining, for example, has not only facilitated the identification of different structures in their minutest ramifications and most intricate combinations, but has made it possible to distinguish between active protoplasm, in whatever form it may be found, and the material formed by it, and has revealed essential differences between cells otherwise apparently alike in all respects. Schwann and Schlerden laid the foundation of histological science by the discovery of cells as the structural unit, and when the knowledge of minute anatomy had reached a certain point the results were systemised by Bichat, who by his general anatomy prepared the way for the cellular pathology of Virchow. Side by side with advancing knowledge of structure has come increasing comprehension of function. Physiology from first to last is based on experiment. It was by experiment that Galen proved that the kidneys secreted and the bladder retained the urine, and learnt the motor and sensory functions of nerves, and that Bell, again, nearly 1700 years later, discovered that the posterior nerve roots were sensory and the anterior roots motor. It was, of course, by experiment that the circulation of the blood was established. The advances made by Haller (1708-77), again, in the elucidation of vital action were based on experiment. It was not, however, till the example was set by Majendi that experiment was systematically employed in the investigation of all the functions. He was followed by Claud Bernard, to whom we owe our knowledge of the vasomotor apparatus and its influence on secretion and nutrition, and with whose name is associated the glycogenic function of the liver, which has been rudely questioned if not overthrown by Pavy; by Ludwig, who elucidated the dynamics of the circulation; by Marshall Hall and Brown-Séquard, who led the way in the experimental investigation of the functions of the various parts of the nervous system which has now reached such a wonderful stage of development. [Sir W. Broadbent here referred to investigations upon respiration, coupling with physiologists the names of Priestley and Lavoisier. He proceeded:]

So far we have been chiefly concerned in following the growth of knowledge relating to healthy structures and normal functions. Facts relating to the effects produced by disease on the different organs could be collected, and the symptoms attending the progress of disease and revealing its nature could be recorded, independently of any comprehension of the processes by which morbid changes were effected. Such accumulation of facts and such observation of symptoms were indeed necessary before study and experimental investigation of morbid processes could be undertaken.

[Sir William Broadbent went on to mention Morgagni, Virchow, Paget, Cohnheim, the use of the microscope and stethoscope, Jenner and vaccination, and the use of the clinical thermometer. He proceeded:]

Another physiological discovery of far-reaching importance to which clinical observation has led up has been the definite determination of the fact that the ductless glands, and probably other glands, supply to the blood some material which plays an important part in the nutrition of the tissues, stimulating or modifying the cell activities. Few histories are more interesting than that of the successive steps by which extract of the thyroid gland was ascertained to cure myxœdema, beginning with the observation that cretinism was associated with goitre, and that the essential feature of this affection—myxœdema—could be induced by extirpation of the thyroid. Upon this, experiment showed that the cause was not the accumulation in the blood of some substance which ought to have been withdrawn from it by the gland, but the absence of some material which the gland supplied. Older than this, and even more important, was the discovery of the part played by micro-organisms in certain diseases. Here, again, clinical observation and reasoning had anticipated Pasteur. The communication of disease from person to person, the incubation period which intervened between the exposure to contagion and the development of symptoms, the successive stages which these symptoms followed and the reproduction in the individual of the poison, had given rise to the zymotic theory, according to which the history and course of these diseases were comparable to fermentation following the addition of yeast to a saccharine solution. Experimental demonstration, however, is now demanded, and the place of theory in medicine is only to suggest and to guide investigation. It was not, therefore, until Pasteur—by the successive steps of his work on the various fermentations on pébrine, the city-borne disease, and on malignant pustule and splenic fever—had demonstrated the powers of micro-organisms, and Lister, by that infinite capacity for taking pains—which, when combined with true insight, constitutes genius—had made the totally unexpected and unforeseen extension of the germ theory to surgical affections; until Koch, again, in 1882, had identified and made visible the corpus delicti of phthisis in the tubercle bacillus that the microbic origin of these diseases was fully admitted and the sweeping character of this new department of knowledge was recognised. We may even claim for clinical observation that vaccination was a standing illustration of the attenuation of a virus, and that it anticipated and pointed the way to the processes by which Pasteur has attained such sensational results in hydrophobia, and by which we hope and believe that other diseases, such as scarlet fever and the fevers generally, will be robbed of their terrors. The bounds of the zymotic theory, properly speaking, have, however, been overpassed, and, indeed, swept away, and diseases such as tuberculosis are found to be caused by micro-organisms which appeared to have no analogy with those originally grouped under the name; but science has pushed the analogy between disease and fermentation still further. Just as alcohol is the potent product of the torula, so it has been ascertained that the products of bacteria are the agents which give rise to the constitutional disturbance of disease, and these products have been separated and identified. Not only so, but just as alcohol, when it has reached a certain proportion, arrests further multiplication of the torula, so do the products of bacteria bring their action to an end, and advantage is taken of this in the antitoxin treatment of diphtheria, which has recently evoked the admiration and challenged the gratitude of mankind. We have still to ask, What is the bearing of all these advances of knowledge on therapeutics, which, after all, is the object of our lives? Until the last few years it has not been easy to answer this question by instances of any very extensive applications of physiology to the treatment of disease, and morbid anatomy was at one time a stumbling-block in the way of therapeutic effort. The pathologist, pointing to an excavated lung or cirrhosed liver, would ask the physician what he could expect to do with drugs against such conditions. But that stage has passed away, and I will not mock your intelligence by other illustrations beyond those just given of therapeutic applications of physiological and pathological knowledge or by arguing that all knowledge of normal processes aids in the comprehension of morbid processes, and that we are in a better position to combat disease when we thoroughly understand its causation and initiation, and follow mentally its development, course, and tendencies. Given the faculty of

Digitized by Google

observation, the insight which penetrates the meaning of the phenomena, the analytical and synthetical powers by which a diagnosis is constructed, the ready adaptation of means to a well-defined end, and the firmness of character required to deal with the frailties of human nature, and the best physiologist will make the best pathologist and the best pathologist the best physician.

[Sir William Broadbent here passed to the consideration of therapeutics and continued:]

The basis of therapeutics is diagnosis, the grasp of the actual condition underlying the symptoms or phenomena, and the greater our command of powerful remedies and the more precise our knowledge of their effects and of the mode in which these effects are produced, the more important does accuracy in diagnosis become. A diagnosis, to be real, implies not only the recognition of the disease which may be present and an accurate appreciation of the morbid changes which may have taken place in various organs, it embraces a knowledge of the nature and intensity of the pathological processes which have been and are in operation, and of the causes which set them going, and also of the results to which they tend. A further element, moreover, enters into the consideration: an estimate, by the aspect of the patient, by the pulse and temperature, and by other subjective and objective indications, of the impression made on the system, and of the resistance which it is capable of to the lethal tendencies of the disease. Year by year we see improvement in this respect; not only that hospital physicians and teachers endeavour to carry diagnosis to a greater pitch of accuracy and a higher point of refinement than ever before, but that the entire body of medical men are trained by improved education and systematic clinical teaching to appreciate and to practise careful diagnosis in their daily work. Diagnosis, we may say, has reached an extraordinary degree of advancement. There are, no doubt, still new fields to conquer, but in the recognition of diseases, local and general, there is not much which seriously concerns the human race which remains to be done. The same degree of knowledge, however, does not extend to morbid processes. Our comprehension of the significance and essential character of inflammation is by no means complete and satisfactory. The part which fever plays and the place which it holds among the phenomena of disease is far from being fully understood. It cannot have been intended by Nature for the destruction of the subject, and we can see distinctly that in some cases it forms a part of the defensive operations; possibly, indeed, its general tendency is defensive, by promoting the production of phagocytes, or possibly a certain elevation of the temperature may be fatal to maleficent organisms which have taken possession of the blood or tissues. We are not certain, indeed, whether in pyrexia the heat-producing oxidation in the structures receives its stimulus from, or takes place at the bidding of, the nervous centres, or, on the other hand, is due to enfeeblement of the restraint which they normally exercise over it, or whether it defies control by the thermotaxic nervous centres.

But here I must stop. I have said enough to show that the much-despised therapeutics, like clinical observation, suggests and stimulates scientific investigation, and I must now take up the last point; the views which guide the medical man at the present day in the employment of remedies. Of course our individual guide is mainly personal experience and observation of their effects. But the human mind is so constituted that it demands reasons, and even our experience finds expression in theory. There is, however, no theory which is supposed to apply to pathological processes and therapeutics in general, like the humoral doctrine of Hippocrates and Galen, the various intro-chemical and mechanical theories, the animism of Stahl, the stimulant, contra-stimulant, or organicist ways of accounting for everything—no theory of universal application. Yes! Homœopathy still, like a belated ghost, haunts the dawn of scientific medicine, and men are still found who wear its doctrines as a cloak for ignorance, or flaunt them as an attraction for the more foolish and credulous of the old ladies of both sexes. But, while our minds are not dominated by any *a priori* conception of a vital principle governing all vital operations, we must not flatter ourselves that we cannot be carried away by fashions in treatment. In our own day, under the influence of Todd, alcohol was largely accepted as the universal panacea, and for nearly a generation mercury was almost banished from the materia medica on theoretical grounds. The last twenty or thirty years have afforded us increased opportunities for the study of syphilitic diseases of the nervous system and of hereditary syphilis because of the abandonment of mercury in the treatment of the primary disease. And if we have no comprehensive theory of disease or treatment we have our small working hypotheses. To one man gout explains everything, and the more hazy or inadequate his idea of what gout is the more satisfactory the explanation. Gout, moreover, is accepted by the public as accounting for everything. The permutations and combinations of which uric acid is capable, and its ingenuity in giving rise to the most varied forms of disease, are truly wonderful. To another man the clue to treatment is acidity or bile or disease of the liver. Names have still a great influence, and the lesson which Galen constantly enforced, that we must treat not the disease but the patient, is as necessary in our day as in his. It does not follow that because we call a pain rheumatic the remedy is salicylate of soda. At one time the action of quinine was supposed to be explained by calling it an antiperiodic, and any tendency to periodicity in the recurrence of symptoms of whatever kind, or at whatever intervals, was considered to be an indication for its exhibition. It is inevitable that our imagination should be impressed by the revelation of the wonderful part which micro-organisms have been found to play in the genesis of disease, and that our thoughts should turn towards antisepsis in our treatment. So far the greatest success has been in dealing with microbes outside the system, as in antiseptic surgery and preventive medicine, and further triumphs are to be hoped for in this direction, as, for example, in the prevention of tuberculosis. We have as yet little evidence of the power of antiseptics to follow and destroy the microbes when they have once got possession of the system. Quinine, however, kills the malarial plasmodium, and we have now the antitoxic serum. Apparently, too, one virus may be antagonistic to another, and an attack of small-pox has often seemed to cure phthisis. We must continue our efforts to apply antiseptic principles, but it is most important that we should not allow ourselves either to imagine that we have obtained effects which have not been realised or to attribute results to antisepsis which may have come from other causes. It is not yet clear that any considerable impression has been made on the mortality from phthisis by guaiacol or creasote; and was not sulphuretted hydrogen injected into the rectum to deliver us from this scourge? It was inevitable, again, that we should be greatly struck by the remarkable power of lowering the temperature possessed by the antipyretic class of drugs. We seem to have within our reach the means of dealing with our most formidable enemy, and it is a great triumph to be able to point out to friends the effect of our remedy on the temperature chart, especially when it has been accompanied by relief of headache and other symptoms. Here it is very important that we should maintain an attitude of cool observation, and not conclude that in bringing down the temperature we have necessarily exerted a favourable influence on the course of the disease. We may have been bringing down also the patient, and it is not so certain that Nature does not know her business when she sets up febrile reaction. I feel myself justified in re-echoing the warning given by Dr. Douglas Powell on this point. But it is time that I should bring this long and disconnected address to a close, and in thanking you for the patient attention with which you have listened to it I congratulate you and myself that we live at a time when the art of medicine has made such progress, when science in its application to medicine has brought such marvellous and such beneficent aid to therapeutics, and when our beloved profession stands so high in the estimation of the world.

YARROW HOME, BROADSTAIRS.—A seaside convalescent home for children, named after the founder, Mr. A. F. Yarrow, was opened on Tuesday last at Broadstairs. A numerous company travelled by special train from Victoria, and on arrival at Broadstairs, after a short service, the home was formally declared open by Mrs. Yarrow. Some two years ago the generous founder of the institution was looking about for the best direction in which to devote a large sum of money for the benefit of children, and became impressed with the fact that while the wants of the very poor are already fairly met by existing agencies, there are many people of very limited means and at the same time highly respectable—too sensitive to seek help from any charitable agency or to let their wants be known outside their own circle—who in times of adversity suffer much. Hence the erection of this new seaside home for the reception of children—fifty girls and fifty boys—of deserving parents.

Address in Surgery,

Delivered at the Annual Meeting of the British Medical Association at London, August 1st, 1895,

BY JONATHAN HUTCHINSON, F.R.C.S. ENG., F.R.S.,

CONSULTING SURGEON TO THE LONDON HOSPITAL, AND LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

ON MODERN ADVANCES IN SURGERY.

MR. PRESIDENT AND GENTLEMEN,—My first words must of necessity be an attempt to express the deep regret which you and I alike feel at the sad event which has been the cause of my coming before you. We had all looked forward with high anticipation to the pleasure of listening to an address on surgery from Arthur Durham. The hand of death has snatched him from us and put a stern veto on our hopes. It is not too much to say that the whole profession deplores Mr. Durham's too early death as a heavy loss to surgical science, whilst to many of us it brings also the sorrow for a much-loved friend. In the year 1750 there was published in London by one of Mr. Durham's many distinguished predecessors "A Critical Inquiry into the Present State of Surgery." Samuel Sharp was not only surgeon to Guy's Hospital, he was a Fellow of the Royal Society and a man of acute and original mind. He wrote good English, he saw for himself, and he travelled, not merely for self-gratification, but in search of professional knowledge. His work was to some extent the result of a visit to Paris, and he displays familiarity with the practice of all the Continental surgeons of his day. His "Critical Inquiry" was received with such favour that it was translated into French, German, and Spanish. I may, therefore, fairly take this book as representing the opinions of the day, and as affording to us fair criteria as to the topics which most interested the surgical world in the middle of the last century. Mr. Sharp thought well of his times and his compeers. In his preface he writes: "Perhaps there never was a period of time in which any art was more cultivated than surgery has been for these last thirty years." This, we may remember, was written when Pott was in his prime and Hunter a young man. It may perhaps not be without instruction for us if I glance for a few minutes at the topics which mainly claim attention. To begin with, he dismissed luxations and fractures with the remark that all eminent surgeons were agreed as to the method of treating them. With an almost similar remark he put aside "tumours, wounds, abscesses, and ulcers," asserting that their treatment is "fundamentally the same in every country of Europe." His optimistic belief that finality had been attained in these large departments is to be regretted, for it much restricted the scope of his interesting "Inquiry." His thirteen short chapters concern hernia, lithotomy, amputations, concussion of the brain, tumours of the gall-bladder, extirpation of the tonsils, hydrocele, and a few others. A small 8vo of less than 300 pages, and in large type, suffices for what he has to say. Let me repeat that what he does say he says well; but how little there is of it, and how restricted are his topics. What a contrast is presented with the almost limitless multiplicity of the subjects which in the present day claim the attention of its successors? Mr. Sharp's chapter on the extirpation of the tonsils contains a strong recommendation of the procedure of this simple measure. He remarks: "There is not an operation in surgery that in my opinion ought to give an operator so much encouragement. It is neither dreadful in the doing nor melancholy in the event." From this remark we may infer much as to his general experience of the major operations of his day. He wrote before the days of laparotomy for intestinal obstruction, and it is possible his thoughts probably went no further than excisions of tumours, amputations, and cutting for stone. Somewhat more than half a century later another important work appeared on the same lines, but far more thorough in character than that of Mr. Sharp. M. Roux, the distinguished surgeon of La Charité, spent a month in London engaged in the diligent investigation of English surgery. On his return to Paris he published the results of his observations. He had seen Laurence, Brodie, and Bell operate; of the two former he speaks as young men. With Cooper, then in his prime, he had held controversy as to the possibility of bony union in fractures of the neck of the femur, and had promised to send him a specimen which should remove all doubt. Between the dates of Sharp's "Critical Inquiry" and Roux's "Relation d'un Voyage" the whole of John Hunter's career had passed. The "Father of Scientific Surgery" had now been twenty years in his grave, and the great work of his life, that triumph of genius and industry, his museum, was already well housed under the guardianship of the College of Surgeons. Roux visited the museum, and he notes over and over again the extraordinary love which English surgeons had for anatomical preparations.

I do not purpose now to occupy your time by any analysis of this work, but I put it forward as a very valuable recapitulation of the surgical knowledge of the day as regards its two most important schools, Paris and London. As my design is to make some comparison between the present and the past, I shall find occasion hereafter to recur to M. Roux's statements in reference to various special subjects. Some of his more general impressions it may, however, be suitable to briefly mention. He held that England and France were really the only rivals in the art of surgery. Germany, Italy, and Holland had each, he admitted, produced their names, but they had been isolated and not of the first rank. It did not occur to him to even mention Austria. Russia was but just emerging from barbarism, and the United States, not yet more than twenty years independent, had given no indications of that successful activity which has been since displayed. He found the London hospitals behindhand as regards the classification of their patients, only one of them (the London Hospital) having as yet attempted to separate medical from surgical cases. London operators he thought skilful, but terribly slow. One of the best he had seen take twenty minutes in the doing of a circular amputation which any Paris surgeon would have finished in a quarter of the time. He thought the attention given to the management of fractures in England much inferior to that in Paris. He much regretted to observe that not only in London, but in some other large cities, special institutions had appeared for the treatment of diseases of the eye. These he thought to be good neither for the profession nor for the patients. Whilst I cannot agree with him in this, I venture heartily to applaud the sagacity with which he detected a weak point in the management of the Royal College of Surgeons ("un vice essentiel de cette institution"). He was amazed that an institution for the advancement of surgery should devote to comparative anatomy most of its lectures and the best part of its museum space. These subjects ought, he held, to find their place in a museum of natural history. Would that he could see it now. The best part of the new wing, erected at vast cost, is now nothing more than a reading-room or study for anatomical students, and its walls are occupied by a collection of skulls and skeletons which has no connexion whatever with our art. In place of a museum of clinical surgery we have a Golgotha of anthropology. This allusion to the present into which I have been betrayed reminds me that I must here leave M. Roux and his book and hasten to another and modern epoch.

In the year in which our honoured veteran, Sir Spencer Wells, then untitled, was the zealous editor of the *Medical Times and Gazette*, I had the honour to be his junior coadjutor. He determined to endeavour to bring to light the real facts as regards the results of operative surgery, and a plan was devised for the systematic publication in a classified form of all operations performed in English hospitals. The scheme was wholly Mr. Wells's, but I was entrusted to carry it out. For nearly three years brief records of all hospital operations, collected, as far as we could attain it, with scrupulous regard to accuracy, were regularly published. I hope I shall be pardoned for adverting to a topic which is to some small extent personal, but I believe that those reports were not without their influence in the development of surgical knowledge, and that they present a more accurate picture of hospitals a quarter of a century ago than can easily be found elsewhere. As such I ask permission to use them, together with the two books which I have mentioned as supplying material for contrast with the present. These reports were commenced in 1855 and came to an end in 1858. The task of collecting the materials was of the utmost use to my own surgical training. I was every day in the operating theatre of one or more hospitals, and in constant confidential communication with the hospital surgeons of the day. The statements published were in most instances revised by those whom they concerned, and the utmost care was taken to assure accuracy. It will be easily understood that in

Digitized by Google

many instances I was cognisant of details which it was not permissible to put in print. In this way I was enabled to form strong and clear opinions on various points in practice, some of which have been borne out by subsequent experience, and others not. Amongst others I well remember that there was a time when Mr. Wells, as well as myself, regarded the operation of ovariotomy as not much removed from manslaughter. We knew of fourteen cases in succession at different institutions, every one of which had ended in the death of the patient. There was a rumour about the same time that a well-known coroner had threatened Mr. Baker Brown that he would hold an inquest in the next case in which he did the operation. Another operation in reference to which I formed a strong prejudice was that of lithotrity. Although at this date Sir Benjamin Brodie had in private practice obtained satisfactory results, and had devoted much attention to the improvement of instruments, yet I could see nothing at the hospitals that was encouraging. A not inconsiderable number of the patients did actually die after it, and of the others it appeared to be the fact that scarcely any were really cured. They were perennial patients, and the same unfortunate man would appear over and over again to be subjected to a repetition of the same tortures. There was no single operation respecting which it was so difficult to secure trustworthy reports, and in many instances the cases which I was obliged to record as "cured" were, I strongly suspected, not really freed from stone. It was, of course, long before the days of litholapaxy, when it was the custom to break a stone into fragments and leave them to find their way out as best they could. The impression which I formed of this operation was such that I determined never to do it, and when, later, I was elected surgeon to the Metropolitan Free Hospital and a good share of stone cases fell to my lot, I invariably performed lithotomy. This rule was continued during my surgeoncy to the London Hospital, and in contrasting my success with that of some of my colleagues, who frequently used the lithotrite, I found nothing to regret. When, however, Bigelow taught us how to complete the operation at one sitting and to remove all fragments, I saw, almost with regret, that lithotomy must henceforth give place. My hands, however, needed practice in the new operation, and I found to my chagrin that I could not do it so quickly and neatly as those could who made it a special pursuit. One patient unfortunately died, and I felt very sorry that I had not cut him. I determined that I would not do litholapaxy *propriâ manu* again, but that I would watch its results in the hands of a specialist friend. From that date onwards I have always on discovering the presence of a stone of a size not demanding lithotomy transferred the patient to my friend. The result has been not a single death, and, what is almost of equal importance, not a single case needing a second operation. All the cases have been adult, if not aged, men, and my list has included two near relatives, two ex-hospital colleagues, two other medical friends, and many strangers. In every instance the recovery has been *cito et jucunde* and the relief permanent. During the same period I have done lithotomy in a few exceptional cases, but they have been only a very few, and in other respects there has been no selection. Lithotrity as practised in our hospitals forty years ago was for the most part a miserable failure; litholapaxy in the present day is, in the hands of our specialists, a joyful triumph. I assure you that I regard the results of my practice in this department ever since I ceased to operate with my own hands with the utmost satisfaction and pride.

If, however, the triumph of lithotrity has been pronounced, that of ovariotomy may yet be held to surpass it. This is in part because at one time it seemed yet more hopeless. It needs some courage to attempt, even in the briefest manner, to sketch the history of this victory, so many are the points in dispute and doubt, and so much of personal feeling is involved. Let me say, then, in beginning what none but a churl will dispute, that to the operative skill, the patient attention to detail, the indomitable determination to go on from good to better, which through a long series of years were displayed by him whom we now honour as Sir Spencer Wells, the credit is mainly due. Yet Mr. Wells was by no means the first in the field, even in what we may consider the modern revival; Mr. Wells and myself did our first operations within two months of each other—he in February, 1858, I in May of the same year. But Mr. Baker Brown had been doing it for several years before, and he was present at both Mr. Wells's first operation and my own. From this date ovariotomy took a new start. Successes were obtained, the cases were brought before our societies, and surgeons began to be hopeful. For many subsequent years it appeared as if the principle of keeping the end of the pedicle outside the abdomen was the main improvement. This plan I had practised and advocated from the first, and I had devised for its better accomplishment a clamp, which came into general use and held its ground for a decennium. Mr. Wells had in the first instance dropped the pedicle into the abdomen, bringing its ends out at the wound, and he considered the latter point an advantage, as keeping open a track for the escape of matter. His first case and mine alike recovered, but his after much "fetid discharge" from the abdomen, and mine with primary closure of the wound. He subsequently used my clamp, and in a letter published many years afterwards very generously acknowledged his indebtedness to it. Mr. Baker Brown also very promptly adopted the clamp. Such having been the circumstances, I may, perhaps, be pardoned if I confess that there was a time when I allowed myself some gratification in the thought that I had myself taken some share in furthering the success of this important and life-saving operation. I bore with such equanimity as I could the discovery that I could not compete with my friend in the ratio of successes obtained, and acting on the rule of conduct that I would never keep a patient in my own hands if I believed that someone else could do what was needed with greater prospect of success, I gave up doing ovariotomies both in public and private, and used to transfer my patients from the London Hospital to the Samaritan Hospital. As to the explanation of my comparative want of success I always felt in some doubt. That I could not keep my experience of the operation on a level with that of Mr. Wells was certain, for he had a special hospital and I only a general one. That lack of the skill which comes only from constant practice was not the only explanation, if indeed the chief, seemed proven by the fact that I had lost some of the very easiest cases which had made no demands on special skill. I was driven to the conclusion that, as surgeon to a large general hospital, and in attendance upon all sorts of cases, and erysipelas amongst the rest, I could not keep myself from risks of contagion so completely as was accomplished by the precautions which were at that time enforced at the Samaritan Hospital. Another disappointment, however, awaited me. The time came when the clamp was discarded, and with it the principle which I had cherished of extra-peritoneal treatment of the pedicle. Operators fell back on the old practice, which had apparently been a great failure, of cutting off the ligatures short and dropping the pedicle into the abdomen. This plan had been tried in a few cases during the reign of the clamp by Dr. Taylor Smith, and with much success. Mr. Wells was induced to resort to it, but soon returned to the clamp. Finally, however, it has gained the day. No one now practises any other method, and the clamp has even been disparaged as unsurgical. It is one of the many difficult problems which changes in surgical practice offer for our investigation to explain why a method of practice which seemed so fatal formerly should be so successful now. In part it may have been that we did not try it fairly, and that the assumption that the tied end of the pedicle must necessarily slough and infect the peritoneum prevented us from giving the method an adequate trial. It may have been that we did not in former times attend sufficiently to the various details included in the expression "toilet of the peritoneum," and it is quite certain that we were at the time ignorant of the use of antiseptics. Probably the truth is that the latter have made safe what was dangerous formerly, and thus it possibly remains to be the fact that the clamp and the extra-peritoneal method which it emphasised did really win the day for ovariotomy at a time when no other tactics would have succeeded.

I must hasten to other and yet wider topics. M. Roux, as I have told you, saw with much disapprobation the beginnings of specialism in London. He found new hospitals for diseases of the eye, which he thought likely to prove injurious to the interests both of the profession and the public. Many years after the date of his visit to our metropolis I had myself opportunities of witnessing the results of this prejudice in the wards of M. Roux's own hospital. I then saw cases of extraction of cataract treated in the open ward and by the hand of the general surgeon. I saw eye after eye lost by suppuration. The same might, I admit, have been witnessed in some of our London hospitals, but not so frequently or at so late a date. Common-sense won

Digitized by Google

the day somewhat sooner amongst us. The victory of specialism in diseases of the eye is now acknowledged by all, even by many who still echo M. Roux's sentiments in reference to many other departments of our art. Can we, however, refuse to recognise the lesson which the modern practice of such operations as lithotrity and ovariotomy teach us? Are there not also many other procedures which stand on precisely the same footing? Would anyone allow an inexperienced surgeon to extract a gall-stone when the services of one who had done many such operations were at hand, or entrust the removal of laryngeal growths to any surgeon, however skilled, who was not specially trained as regards that operation? If we could get the gross statistics of ovariotomy and lithotrity for the whole kingdom, I much fear that the ratio of success would be found to fall lamentably short of that habitually secured by our best specialists. I designedly speak of specialists rather than of special hospitals, for it is quite possible that the latter may, when the staff is large in proportion to the number of beds, cease to afford the advantages as regards individual experience which they are designed to do. Good specialists are, besides, sometimes developed quite independently of special institutions. The late Mr. Gutteridge of Birmingham is reported to have made a proposal that he should be appointed lithotomist to the United Kingdom for the reason—almost sublime in its simplicity—that he could do the operation better than anyone else. He had never had any hospital appointment, yet I have been told by those who knew him well that his allegation was no mere empty boast. The remarkable results in litholapaxy in children obtained by Dr. Kegan in India, those of Sir Henry Thompson in lithotrity in adults, those of more than one in brain surgery, and those of Mr. Mayo Robson in operations on the gall-bladder, are all of them, I think, good examples of what we call personal specialism. Of these personal specialists it may further be alleged that not only do they develop remarkable skill themselves, but they almost invariably succeed as teachers. Most of those whom I have named have in this direction had a wide influence, and there was a time when surgeons flocked from all parts of Europe to learn from Mr. Spencer Wells how to do ovariotomy with success. A man who thoroughly understands his subject in its details can treat it with an efficiency and ease which are wholly unattainable by others. To encourage specialism in many branches of operative surgery is, then, I cannot but think, in consonance with common sense and common humanity.

If any enterprising journal of the present day should undertake the publication of operation statistics on the plan which I have described, as devised by Mr. Spencer Wells thirty years ago, we should have before us materials for a most interesting comparison with the past. In the first place, I do not doubt that we should be astonished at the enormous increase in the number of operations. Formerly one operation day a week was thought sufficient for most hospitals; then it increased to two, and now I suppose there are few institutions in which every day is not so regarded. Nor is this only in hospital practices. Operations in private practice have probably increased in still greater ratio. I well remember the institution of the first nursing home in London, and a very modest one it was. Before that we had to take our patients into hotels or private lodgings. Now, in addition to such luxurious establishments as Fitzroy House, we have homes and hotels for the sick without number. There are West-end streets in which every other house is so occupied. The patients are, I believe, though by no means exclusively, yet in great majority, surgical cases. These institutions are, without exception, managed, if not to perfection, at any rate with a degree of excellence above what was dreamed of half a century ago. If I praise the nursing homes, what shall I say of the nurses? Not a home is opened but it becomes provided at once by a troop of beings who, fair, intelligent, gentle, and indefatigable, would seem to have been created for the special work. What this class of young women did before nursing was invented is a constant puzzle to me. Its difficulty is equalled only by the question as to what becomes of them, for I never saw one who was even approaching middle age.

If I am asked as to what are the special operations which have increased, the reply must be that they are most various, and that on the whole they are such as conduce most definitely to mitigate sufferings and to prolong life. Permit me to take one as an example. It shall be one in which the development of sound doctrine as to pathogenesis rather than augmented surgical daring has gained the triumph. No one ought now to die of cancer of the tongue; nothing except neglect of the early stage can bring about such a result. It is the doctrine of the local origin of cancer and of a precancerous stage which has placed us in this position. In former days no operations were with the rarest exceptions performed for this disease; and if they were, it was in the late stage, when, to use the forcible expression which I have quoted from Mr. Sharp, the procedure was both "dreadful in the doing and unfortunate in the event." Cancer of the tongue was, in fact, hardly ever diagnosed until it was too late to operate. One of our most popular surgical manuals taught that enlargement of the lymphatic glands in the latter afforded one of the best means of distinguishing between syphilitic and cancerous disease. We should now regard it as evidence of almost culpable delay, and as implying that the case had advanced too far for surgical aid. That distinguished surgeon, Mr. Syme, was a pioneer in this branch of operative surgery as in many others. I well remember to have formed once one of a crowded audience in the theatre of the Edinburgh Royal Infirmary assembled to witness one of the first of these operations. The symphysis of the jaw was sawn through and its halves dragged. The operation was most dexterously done; it was most complete, but at the same time it was most formidable. The patient died a few days afterwards, and he was, I believe, the third in succession that the operator had lost. He, as a conscientious man, determined never to attempt it again. There are surgeons now living—more than one—who can boast of operations for cancer of the tongue by the score, if not by the hundred, and with no appreciable mortality. They are not, however, cases such as those which alone Mr. Syme attempted; a majority of them are cases in which the operation is in itself a mere trifle—the excision, it may be, of only a very small part of the organ. Year by year the number of cases in this category increases, and that of those in advanced stages diminishes. What hinders that all cases of cancer of the tongue should be submitted to operation in the earliest stage? Nothing excepting defective diagnostic capacity on the part of members of our own profession. The fault is but rarely on the part of the patient. I never yet met with a patient to whom it was kindly yet confidently told, "You have got cancer," who did not gladly and without delay assent to the operation.

In another department of surgery our work has also enormously increased, partly in connexion with improved methods and partly from sounder principles of diagnosis. In the case of the tongue is improved diagnosis only in that of the female breast it is that in large part, but in still larger the modern methods of dressing which now enable us to promise to the patient a painless operation and a speedy convalescence. There never was anything formidable in the performance of an excision of the breast, but I well remember the time when the prospect of a febrile illness with troublesome suppuration and a succession of dressings only less distressing to the patient than the operation itself, acted as a very powerful motive to the surgeon for delays, which were very dangerous. No case was ever operated upon until the diagnosis was as clear as daylight, and until in but too many instances disease was far advanced. The class of symptoms by which our textbooks taught us as students to recognise cancer of the breast were for the most part, as in the case of the tongue, those present only in the late stage. Those which we now teach to our students are wholly different. What would be thought of the surgeon in the present day who should inculcate reliance upon the retraction of the nipple, the saddle-leather condition of the overlaying skin, or the unhealthy condition of the ulcer? We now trust solely to the trained finger to recognise the character of the induration, and we lay down an inexorable precept that if there be any reasonable doubt the breast should be removed. Our patients, as a rule, accede without much reluctance to our recommendations, for they know from general report that the modern operation is a mere trifle. The result of this change of practice is that the statistics of cancer of the breast must be rewritten. Those collected so laboriously three or four decades ago are no longer in the least applicable to our present results. Permanent recoveries after removal of the breast for scirrhus, as after those of part of the tongue for epithelioma, are now common in the practice of all operators. So much has been said or implied in the discussion of the last two topics that the present becomes a suitable place to introduce a few remarks upon the all-important topic of the educational training of the surgeon of to-day. The great examining bodies which exercise such a large influence over the destinies of our profession in presiding at

Digitized by Google

its admission portals have recently decreed that the education of the student shall be extended over five years. For myself I may say that, although in committees and council-rooms I have always consistently given my vote in favour of this addition of a year, I have never been a warm advocate of the measure. It has always appeared to partake too much of the faith that if you only keep a horse long enough at the water you can make him drink. The additional year must make medical education more expensive and may possibly hinder some of precisely the class which we wish to attract.

The Baillie Lectures
ON
DROPSY.

Delivered at St. George's Hospital on June 19th and 26th and July 3rd, 1895.

BY W. HOWSHIP DICKINSON, M.D., F.R.C.P. LOND.,

HON. FELLOW OF CAIUS COLLEGE, CAMBRIDGE; CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE III.

Delivered on July 3rd, 1895.

GENTLEMEN,—The next form of the dropsy of pressure is cardiac; the immediate cause of this is capillary stagnation due to venous obstruction. The right side of the heart is the first place where the returning blood is liable to meet with hindrance, and theoretically the right side should have more to do with dropsy than the left; but practically the left side with its greater liability to disease takes precedence of it in this respect. Whether we find mitral constriction or mitral regurgitation, the result is much the same in obstruction to the pulmonary circulation; this stands in the way of exit from the right ventricle, and the over-loaded right side stands in the way of exit from the systemic veins. The nearer the obstruction is to the venous exit the more readily dropsy supervenes. If the mitral valve be between the two and holds good it does a great deal, as perhaps it was intended to, to keep the venous return free and dropsy absent. We see this in aortic regurgitation. The left ventricle gets over-filled and over-stretched during diastole by the blood which is rushing back into it through the aortic opening at the very same time that blood is pouring in, in due course, through the mitral. It might be thought that this crowding of the cavity would make a block the effects of which would reach the veins, but it does not appear to be so. So long as the mitral valve is capable of doing its duty dropsy is absent. I have my eye upon a case now which has been under my observation for the last thirty years. There is extreme aortic regurgitation with an enormous left ventricle. There is no dropsy, and never has been. If the mitral valve should give way and a mitral murmur present itself, then we shall have dropsy, and probably not before. Among the relations of the diseased heart to dropsy there is one which I think has been too much lost sight of—it is this: hypertrophy of the left ventricle is antagonistic to dropsical effusion. This is most markedly seen, as I shall presently show, in renal disease, but is to be recognised in other circumstances. The method is obvious. The ventricle has a double action; it not only drives the blood into the arteries by its contraction, but by its expansion it pulls the blood out of the veins. As it opens it draws upon the left auricle and indirectly upon the right side of the heart, lungs, and systemic veins. The suction power of the ventricle must be increased with the thickness of the wall, just as a ball syringe expands with the more force the thicker it is. I must not dwell further upon cardiac dropsy; as necessarily ensues from its mechanical origin it is earliest found where the veins are at the greatest disadvantage—namely, the lower extremities. If œdema begins with puffiness of the face we may be sure it is not cardiac. Nothing tends more to the increase of this kind of dropsy, and, indeed, of renal dropsy also, than water in the pleuræ, which compresses the pulmonary vessels and adds to the obstruction already existing. I have often had the chest tapped in such circumstances with obvious and immediate advantage in this respect. While upon tapping let me say this: puncture the abdomen whenever you see reason for it; it relieves dyspnœa and the lower extremities, is generally harmless and often beneficial; but beware how you meddle with the legs. So readily is cellular inflammation set up in these cases, and so apt is it to prove fatal, that acupuncture carries as much danger as a capital operation, and should never be lightly undertaken. I have sometimes heard it proposed to tap the legs on the ground that the abdomen would be thus relieved. I believe this to be a mistake.

I may here touch, however briefly, upon the general treatment of cardiac dropsy. Before all things it is necessary that the horizontal posture should be enforced unless there are special circumstances, by way of dyspnœa or angina, which forbid it. The defective heart may be able to conduct the circulation on the level, but not vertically. The good of this simple measure is great. In the next place we must do two things simultaneously—relieve the vessels and reinforce the heart. Relieve the vessels by mercurials and hydragogues, and spur the heart with cardiac tonics. Do not waste your time, or rather your patient's, by tinkering with mere diuretics. Diuretics are futile unless they have, like digitalis and squills, an especial cardiac action. Of all the remedies for cardiac dropsy none approaches in value the time-honoured pill of Baillie, fitly commemorated in a Baillie Lecture. This consists of blue pill, squills, and digitalis; the digitalis helps the heart and the mercury unloads the vessels. The effects of this remedy are often marvellous; I have seen, not once only, but many a time and oft, general and extreme cardiac dropsy entirely removed by its means. There is nothing I like better to treat than cardiac dropsy, for I feel that I can see my way and generally do good. You may if you please make use of calomel or the green iodide of mercury instead of blue pill; the essential thing is to give together mercury and digitalis. With children, to whom pills are a difficulty, I have often given with the same results the same thing in a liquid form; liquor hydrargyri perchloridi, infusion of digitalis, and tincture of squills. Be it remembered that cardiac dropsy is generally connected with mitral disease, the valvular lesion with which digitalis is especially useful.

The next division of the subject comprises dropsies dependent on, or at least connected with, changes in the blood; among them is renal dropsy and that of chlorosis. It may be said in general terms that renal dropsy and cardiac dropsy have this essential difference: cardiac dropsy is due to diminished absorption, and renal dropsy to increased exudation. Renal dropsy is more complicated than that of heart disease; conditions of altered blood are involved with questions of altered mechanism; there are several factors to be considered and some discrepancies to be reconciled. In the first place there is a general inverse ratio between the amount of dropsy and of urine; the less urine the more dropsy. But this does not always hold good. In obstructive suppression, say, from renal calculus, though urine may be totally absent for many days, even for a fortnight, there is usually no trace of dropsy of any kind. With nephritis, where dropsy is so usual a concomitant, it sometimes happens that this result is absent where we should most expect it. There is a very acute and fatal form of the disease which I have seen after scarlet fever in which dropsy may be totally, or almost totally, absent, notwithstanding that the urine may be scanty almost to suppression. Death is quickly brought about by uræmia, but dropsy is conspicuous by its absence. Such cases are sufficient to show that the ordinary rule that the dropsy increases as the urine diminishes and *vice versâ* is not invariable, but that other conditions beside the exit of water by the kidneys have to be taken into account. In a paper to which I have already referred, and to which I may appeal for particulars, I gave a number of sphygmographic observations bearing on the relations of blood-pressure and renal dropsy. The conclusions are briefly these: renal dropsy arises together with a certain increase of arterial pressure which appears to be essential to the process; the increase of pressure with early dropsy is not so great as obtains later, but nevertheless is distinct; when under the depressing effect of the disease the force of the circulation is diminished instead of being increased then dropsy is absent: we see this in obstructive suppression which is attended with a failing pulse, death

Digitized by Google

by syncope, and a heart uncontracted after death. I regret that I have no sphygmographic evidence bearing upon this, but the failure of pulse and heart are sufficiently apparent. It would seem that a certain force is required for the accomplishment of the transudation which constitutes renal dropsy, failing which this does not occur, however other circumstances may invite it. Vomiting and diarrhœa may take its place.

The dropsy of kidney disease is evidently connected with the retention of renal excreta, which exert some special action upon the capillaries which at once increases transudation and hinders the circulation. This is not inflammation, but may remotely resemble it, or we may regard it as akin to secretion and as tending to relieve the blood of its morbid elements. The attendant hindrance I have dwelt upon in the first lecture, together with its effect upon the arterial system. The association of dropsy with this difficulty points significantly to its position in the capillaries rather than the arterioles. It is improbable that the transudation, which is necessarily of capillary origin, would be thus promptly poured out were there any considerable constriction of the arterioles to cut off the blood from the ultimate vessels. Among the circumstances which conduce to early renal dropsy is the state of the respiratory organs, which is commonly found with this condition. In a large proportion of cases there is broncho-pneumonia or some allied condition, which must assist the process by hindering the return of venous blood.

Three stages are to be recognised in the natural course of renal dropsy: its *accession*, its *removal*, and its *reappearance*. This division, of course, applies only to cases which become chronic and go on to the latest issues of the disease. Numbers happily get well shortly after the outset; for such there are no subsequent stages; others are debarred from them by early death. Taking the instances where the kidneys are irrecoverable and yet allow of a protracted existence, what happens is this: the heart and arteries slowly become hypertrophied, the arterial tension increases, the pulse hardens, the urine becomes superabundant, and the dropsy lessens and then disappears. With the access of the disease we have the tension increased to a certain degree and with this dropsy; with a further increase of tension and concomitant changes in the heart and arteries the dropsy goes. This result of the *vis medicatrix naturæ* is often placed to the credit of the last drug or the last medical attendant. How is it brought about? Probably in two ways; the increased blood-pressure is a diuretic of no mean efficacy, and the increased expansile power of the hypertrophied left ventricle draws upon the veins and pumps out the waterlogged vessel. But this is not the finish. The last scene of all that ends this strange eventful history is heart-failure and a return of dropsy which is now more cardiac than renal. The beneficial part of the process can be conducted only so long as the mitral valve remains efficient. A time comes, if the patient lives long enough, when the heart stretches under the strain and the mitral orifice becomes too wide to be closed by the mitral flaps. Then comes regurgitation, a mitral murmur, a return of dropsy, which often invades the thoracic cavities, often pulmonary apoplexy, and all the circumstances of mitral disease. Pulmonary apoplexy and hæmoptysis may ensue simply from renal disease without any affection of the heart excepting what renal disease entails. I have given examples of this in the paper that I have more than once referred to.

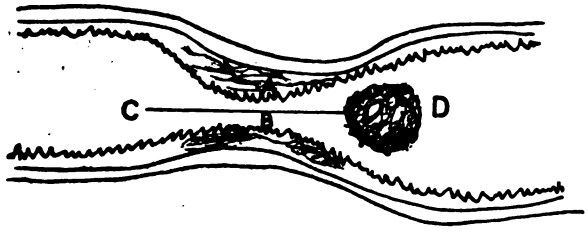
The treatment of renal dropsy is by no means unsatisfactory, since we often have with us a strong-siding champion—Time. We must not be guided solely by *a priori* reasoning or theoretical considerations, but largely by experience. We have to trim and adjust and pursue a system of compromise. We have anæmia on one hand and uræmia on the other, and must steer between Scylla and Charybdis. We have to depurate, to dehydrate, but not to anæmiate. We must evacuate, but not exhaust. "Spare diet and spring water clear" may purify the blood, but are not remedies for anæmia. Watery purgatives, compound jalap powder, sulphate of magnesia, and under extreme circumstances elaterium, may be given periodically and alternately with hot-air baths. Sudorifics in the shape of drugs are useless as remedies for dropsy, but I have known this, when obstinate and extensive, to be entirely removed under the influence of hot air, which I have been in the habit of applying only below the knees: the effect is general and sufficient without being excessive. Of the medicines of the diuretic class the only one of special use is digitalis, and this is so valuable that I have laid down a rule for myself from which I seldom depart—if there be dropsy in the course of renal disease give digitalis. This is not merely a diuretic, but probably has an action on the cardio-vascular system which is beneficial under the circumstances. A very low diet does not do; I give fish generally, and have often exchanged it for a little meat with obvious advantage. The treatment of renal disease is often overdone in the way of taking too much out of the patient and not putting enough in. For the more chronic cases iron is generally beneficial; the perchloride may be conveniently associated with digitalis, and enough sulphate of soda or of magnesia to obviate any constipating effect. I may add a word about tapping which is much what I have said in reference to cardiac dropsy. Tap the pleuræ or the peritoneum with confidence, but leave the legs alone. Relieving the abdomen is often the best way of relieving the lower extremities, for it takes the pressure off the vena cava. With regard to the pleuræ, by removing fluid from them we achieve two ends: not only do we ease the breathing, but by taking pressure off the pulmonary vessels we facilitate the return of venous blood, and thus promote the absorption of dropsy fluid in every part of the body.

Allied to the dropsy of renal disease is that of chlorosis; both are essentially dependent on the failure of a natural excretion and its retention in the blood. I have no time to dwell upon this, but may briefly say that one way in which the toxic agent acts, as does that of kidney disease, is by increasing the arterial tension. It took me by surprise when I found by applying the sphygmograph in this variety of dropsy that with these pallid and feeble creatures given to fainting, as full of murmurs as an Æolian harp—"most musical, most melancholy"—the force of the pulse was increased instead of diminished. It has long been known that these subjects of green sickness were the better for being purged, and for some time suspected that a toxic retention was concerned in the production of the symptoms. In general estimation this toxic element is of uterine origin, and I daresay it may largely be so, but I have often heard Sir Andrew Clark maintain that it was alvine, and thus explain the benefit derived from cathartics. My object is chiefly to show that together with œdema in chlorosis we have increased arterial tension where we should least expect it, and recognise a similar attitude of dropsy and vessel to that which pertains to renal disease. All this helps to explain what we have already learned from experience, that whatever else we do in chlorotic anæmia our endeavours must be to rid the blood of its morbid superfluities, and stimulate the eliminative function of the uterus. Thus we find other warrant than that of experience for conjoining aloes with the necessary iron, and only find in new inquiry fresh reasons for the time-honoured practice.

A MODIFICATION OF THE OPERATION OF ENTEROPLASTY FOR SIMPLE STRICTURE OF THE INTESTINE.

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,

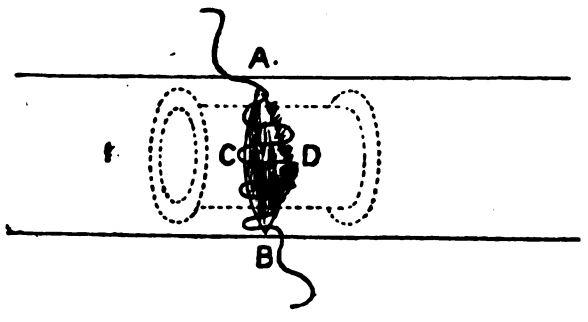
SENIOR SURGEON TO THE GENERAL INFIRMARY, LEEDS; PROFESSOR OF SURGERY, YORKSHIRE COLLEGE; AND MEMBER OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.



THE method of overcoming stricture of the pylorus by longitudinal section and transverse suture of the incision, originally performed by Heineke and afterwards followed up by Mikulicz, was first applied to a case of simple stricture of the intestine by Mr. H. Allingham.[1] The modification of the operation by the use of the bone bobbin will, I think, be found to present the following advantages: (1) rapidity of execution, since only two continuous sutures are required—one to unite the mucous margin, the other the serous; (2) an immediately patent and efficient channel, preventing tension above the newly joined gut; and (3) protection to the line of sutures until the lymph has become partly organised. The following case is of interest, not only from

[1] THE LANCET, June 23rd, 1894.

Digitized by Google



the operative point of view, but from the history of antecedent ulceration of bowel with perforation and recovery.

A thin, delicate girl aged sixteen was sent to me by her medical man, Dr. J. Russell of Batley, on account of a fæcal fistula in the right cæcal region, through which pus and liquid fæces had been passing for some months, during which time she had been gradually losing weight and strength. She gave the history of having had an illness eighteen months previously, when a swelling with tenderness developed in the right side of the abdomen. She had diarrhœa and was feverish, and was told that there was inflammation of the bowels. After some weeks an abscess developed over the cæcum and was opened, a quantity of foul pus being let out. A week after the abscess had been opened fæcal matter began to be discharged from the wound, and this had continued since, though the bowels had been occasionally moved through the anus. On admission to hospital the patient was extremely thin, her bones showing visibly under the skin. There was a fæcal fistula midway between the umbilicus and the right anterior superior spine of the ilium, and the skin around the opening was excoriated, red, and inflamed by the irritation of liquid fæcal discharge and pus. The abdomen was quite flat, and no tumour could be felt. Charcoal administered by the mouth appeared at the fistula in thirteen hours. On July 10th, after laying open the rather extensive sinuses leading from the fistula, scraping them freely with a Volkmann's spoon and as far as possible asepticising them by means of a 1 in 1000 perchloride solution, the abdomen was opened by an incision of three inches, the fistula being the centre of the incision. Adhesions were separated by the fingers and the affected gut brought outside the wound, the peritoneal cavity being protected by sponge packing. The fistula was in the ileum, and while the fingers would easily pass upwards nothing larger than a No. 12 catheter would pass through a stricture fully an inch in length just below the fistula. After passing a director through the stricture, which was evidently cicatricial, it was divided in the direction of the length of the bowel. A decalcified bone bobbin was then inserted and the cut edges were brought together transversely over it, as shown in the diagrams. A continuous catgut suture was

First stage, showing incision from fistula D through to C.

used to unite the mucous margins, and a silk suture the serous surfaces, thus restoring the continuity of the intestinal channel. After carefully cleansing the surrounding structures, the peritoneum, aponeurosis, and skin were apposed

Second stage, showing sides of incision A B drawn apart and ends C D.

in the usual manner. The patient suffered very little from shock, and the bowels were moved naturally on the second day. The deeper parts of the wound healed by first intention; the superficial by granulation. The patient's general condition began to improve at once, and she has never had any bowel trouble since. When seen six months later, she looked a picture of health, had gained her usual colour and flesh, and expressed herself as quite well.

Remarks.—Simple stricture of the bowel is sufficiently rare to make it worth while reporting a single instance; but this case is also of interest from an operative point of view—not simply from the success of the modification of the operation by the use of the bone bobbin, but also because it shows that a plastic peritoneal operation may be undertaken with some prospect of success, though the way into the abdomen be through a foul abscess, if, as in the present case, the walls of the abscess and the surrounding parts be purified before the abdominal cavity is opened.

Leeds.

TWO CASES OF SEPTICÆMIA DUE TO MIDDLE-EAR DISEASE; OPERATION; RECOVERY.

BY W. GIFFORD NASH, F.R.C.S. ENG.

CASE 1. *Septic pleuro-pneumonia following a blow on the head in a boy suffering from otorrhœa.*—A boy aged twelve, who had had otorrhœa for five years, was boxed on the ear on June 16th, 1892. This was immediately followed by headache and seven hours later by vomiting. Next morning headache, photophobia, fever, and delirium were present. Twenty-four hours after the blow I found him lying curled up in bed, objecting to light and interference, delirious, very flushed, and with a temperature of 103° F. and pulse 180. Half an hour later my partner, Mr. Kinsey, gave him chloroform, and I shaved the scalp and forcibly syringed out the right ear, removing a small granulation polypus. Three leeches were applied behind the ear and an icebag to the head. On June 18th he was still feverish, but there was no delirium. He was seen in consultation by Mr. Henry Morris, and with his sanction I trephined and gouged out the mastoid antrum. The dura mater covering the roof of the antrum was also exposed and found to be healthy. No pus was found. On the 20th there were frontal headache and pain in the right shoulder, as also a dry hacking cough suggestive of pleurisy. On the 21st the cough and pain continued. The temperature was 103·4°, the pulse 120, and the respiration 48. On the 22nd the temperature was 104·6°, the pulse 144, and the respiration 60. Pleuritic friction was heard over the left lower lobe and right upper and middle lobes, with numerous scattered patches of tubular breathing; there was also sweating. It was evident that septic pleuro-pneumonia was present. I proposed to explore the lateral sinus, and, if I found it thrombosed, to tie the internal jugular vein. The trephine was applied to the mastoid process over the lateral sinus. This did not pulsate, but looked healthy. A hypodermic syringeful of blood was drawn off, showing that the sinus was not thrombosed. When the needle was withdrawn blood spurted from the puncture. The wound was closed and nothing further done. From June 22nd until the end of July the case was desperate. There were repeated fresh patches of pneumonia with elevation of temperature to 103° or 104°; the pulse varied up to 144, and the respiration up to 72. At one time tubular breathing and friction were heard over the whole of the right lung and lower lobe of the left. The expectoration was fetid, and there were profuse sweating and extreme emaciation. From this desperate condition he gradually recovered. The treatment consisted of milk, eggs and brandy, with quinine and digitalis. During August there were slight occasional rises of temperature. On Aug. 31st he got up, and on Oct. 1st he was allowed out of doors. He then looked as well as he did before the illness. There was no discharge from the right ear, and he could hear a watch tick at 12 in. The right side of the chest was much contracted. In August, 1894, he was in perfect health; the chest showed no sign of contraction; there was no deficiency of expansion or diminution of breath sounds, and no discharge from the ear.

Remarks.—I do not claim that the surgical measures adopted had anything to do with the recovery of this patient, but I believe it would have been culpable to have neglected them when it is considered how fatal these cases are when treated by medical means. There can be very little

Digitized by Google

doubt that the attack of pleuro-pneumonia of both lungs was set up by the blow on the head, as severe cerebral symptoms set in immediately after it was inflicted. It would appear as if the blow had dislodged some septic thrombus from the middle ear and produced thrombosis of some vein or veins entering the lateral sinus, from which septic emboli were carried to the lungs. The source of the sepsis I believe to have been sewer gas, as the house was proved to be very insanitary. Within nine months there occurred in the house one case of pelvic cellulitis, one of diphtheritic sore-throat, two other sore-throats, two cases of acute otitis media, and two of acute rheumatism. All these, I believe, may be caused by sewer gas. The symptoms of acute rheumatism and septicæmia bear such a close resemblance to one another that I need not do more than refer to them. An interesting feature of the case was the absence of rigors, which are usually considered to be diagnostic of septic thrombosis of the lateral sinus. The question arises, Would it have been better to have ligatured the internal jugular vein? I think it would, even in the absence of proof of thrombosis, for it would probably have cut short the illness and diminished the risk to life arising from the extensive inflammation of the lungs.

CASE 2. *Subdural abscess and septic thrombosis of the lateral sinus; drainage of abscess and sinus; ligature of internal jugular vein; recovery.*—A boy aged fifteen had suffered intermittently for two years from left otorrhœa, which had been treated with antiseptic lotions and powders. A granulation polypus had been removed from a perforation in the upper part of the membrana tympani during the previous summer. On March 20th, 1894, he was supposed to have caught cold, and on the 23rd he began to suffer from earache and headache. On the 29th his temperature was 102° F. There was no loss of appetite, and no sickness or shivering. I first saw him on April 1st and found him in bed, flushed and drowsy; he objected to light and was very deaf. His temperature was 103·6°, the pulse 90, and the respiration 24. The left side of his face was puffy. The discharge from the ear was most offensive. There was slight tenderness over the mastoid antrum and cells, and marked tenderness over the large vessels in the neck. There were no physical signs of any lung or heart affection, and no cough or pain in the chest. There was commencing optic neuritis. After consultation with Mr. Kinsey I operated. First a small trephine was applied just above and behind the meatus, and the middle fossa of the base of the skull was opened. The dura mater was found to be healthy. Next, the mastoid antrum was opened. The bone behind this was very soft, and whilst gouging it a most offensive smell arose. An abscess was opened lying between the bone and the lateral sinus, and about two drachms of foul-smelling pus were evacuated. The wall of the lateral sinus was thickened, discoloured, and sloughing. A free escape was provided for the matter. In the absence of rigors it was not considered necessary to tie the internal jugular vein. Next morning the temperature was 100·4° and the pulse 80. About noon he had a rigor and the temperature rose to 104°. At 3 P.M. I tied and divided the internal jugular vein at about the level of the cricoid cartilage. At that point the common facial vein joined it. There was a free current in the facial vein, but none in the jugular, above their junction. The ligatures were applied above their junction. The ear wound was then reopened and the wall of the lateral sinus cut away, exposing a firm, dark blood-clot filling the sinus. The same evening I was laid up with influenza, so that for the greater part of the further treatment and notes I am indebted to Mr. Kinsey. After this, symptoms supervened which gave rise to considerable anxiety as to whether or not a cerebral abscess was forming. The boy became very emaciated. On the 11th the stitches were removed from the wound in the neck, which had healed by first intention. On that day he began to complain of frontal headache, was very restless, and vomited. He also became drowsy, in consequence of which, on the 15th, the mastoid wound was reopened and enlarged. All granulations were scraped away and about two drachms of pus let out from the occipital portion of the lateral sinus. A probe was passed as far as the torcular Herophili and caused slight bleeding. A drainage-tube was inserted in the sinus and the middle ear thoroughly scraped out. On the 17th he had a rigor, which was followed by a swelling on the left side of the neck, which spread upwards over the face and downwards below the clavicle. On the 19th an incision was made in the swelling in the neck, and some foul-smelling pus evacuated. After this all went well, and by May 16th all the wounds were healed.

Remarks.—This case exemplifies an interesting sequence of events—viz., chronic otorrhœa, suppuration in the mastoid antrum, subdural abscess, and thrombosis of the lateral sinus. The course of events, modified by treatment, was as follows: (1) The subdural abscess and mastoid antrum were cleared out and drained, but already the septic inflammation had involved the lateral sinus; (2) absorption of septic material from the thrombus necessitated ligature and division of the internal jugular vein to cut off the source of infection from the general circulation—the lateral sinus was opened to permit of the escape of the breaking-down clot; (3) it was necessary to reopen and enlarge the mastoid wound to allow pus to escape from the lateral sinus; and (4) the subcutaneous abscess in the neck was opened. The cause of this abscess seems to have been one of two. Either it was cellulitis due to septic material carried by the lymphatics from the wound behind the ear, or it was due to the breaking down of the clot in the jugular vein, between the base of the skull and the ligature.

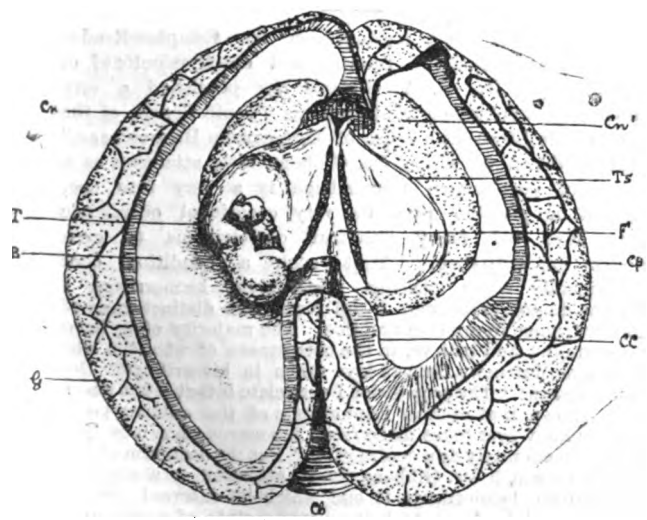
Obliteration of the left internal jugular vein, by clot or ligature gives rise to less disturbance of the cerebral circulation than obliteration of the right vein, as the superior longitudinal sinus usually enters the right lateral sinus, which is then much the largest. The abnormally low entrance of the common facial vein into the jugular was also of interest, as through it the blood coming from the brain through the angular vein was able to reach the jugular below the ligature. The question arises, Should I have ligatured the lateral sinus outside the torcular Herophili, as is advised by Mr. Arbuthnot Lane? I think it would have been wise to have done so, and certainly better surgery. Suppuration must have occurred as far as the torcular Herophili, and one sees no reason why it should not have gone on extending further. In fact, it probably would have done so had not a drainage-tube been introduced into the sinus. The risk incurred by ligaturing the sinus must be small compared with that from the extension of the septic thrombus.

Bedford.

A CASE OF

TUBERCLE OF THE LEFT OPTIC THALAMUS EXHIBITING INTENTION-TREMOR, AND ATTACKS OF TETANOID RIGIDITY; NECROPSY; REMARKS.

BY ARNOLD J. EDWARDS, M.D. VICT.,
RESIDENT MEDICAL OFFICER TO THE CHORLTON-UPON-MEDLOCK DISPENSARY, MANCHESTER.



A BOY aged six years was admitted as a home patient at the Chorlton-upon-Medlock Dispensary under my care on Dec. 17th, 1894. The patient was apparently quite well until seven weeks before admission, when the mother noticed that he dragged his right leg on walking. Two or three days after this it was observed, when he was taking his food, that he held the spoon in his left hand, and upon his mother insisting that he made use of the right hand for that purpose this latter hand began to tremble. At first the trembling was slight, but it gradually got more and more marked. For the last three weeks he had complained of severe frontal headache, and there had been vomiting for the last four days. Lately, also, he had not seemed to see things well. The father died two years ago of apoplexy. The mother gave a history of four miscarriages out of eight pregnancies, and had had a sore-throat for six months at a time. The mother's father died of phthisis. On admission an exceedingly well-marked, coarse, jerky tremor was seen in the right arm on movement. This disappeared entirely when the arm was at rest. The movements came largely from the shoulder. There was no nystagmus or syllabic speech. The right arm and leg were distinctly weaker than those of the left. There was no facial paralysis. There was well-marked and persistent ankle-clonus on the right side, but ankle-clonus was not obtained on the left. Both wrist-jerks were present and about equal upon the two sides. The epigastric, abdominal, cremasteric, and plantar reflexes were all obtained, but showed no difference on either side. There

Digitized by Google

was marked rigidity noticed on passive movement of the right knee-joint. The patient had difficulty in standing unsupported, but closing the eyes did not increase it, nor was there any sign of reeling in one or other direction. With assistance he was able to walk, and the gait was distinctly ataxic. Sensation was universally normal. The bladder and rectal functions were normal. There were no signs of congenital syphilis, and the lungs appeared quite healthy. On December 19th the vomiting had quite ceased under bismuth, but treatment had in no way influenced the headache. On the 22nd there was well-marked optic neuritis of the left eye. There appeared also to be inflammation of the right nerve, but of this I could not be quite certain, as conjunctivitis with a slightly cloudy cornea was present on that side, and the concomitant blepharospasm also rendered ophthalmoscopic examination exceedingly difficult. The other cranial nerves appeared to be normal. Towards the close of the somewhat prolonged ophthalmoscopic examination the patient was suddenly seized with an attack of tetanoid rigidity. He became unconscious, the head was bent back, the spine arched, and the whole body became extremely rigid; the teeth were clenched and both eyes were turned to the right. The face preserved its natural colour. This condition was kept up for about three minutes, and then the muscles gradually relaxed and there was a return to complete consciousness. This tonic condition was not succeeded by any clonic contractions. The mother now told me that he had three similar attacks during the preceding night. I put the patient on large doses of iodide of potassium, combined with mercurial inunctions. On the 23rd he had three attacks of tetanoid rigidity between the hours of six and eight in the morning, the last one being the severest experienced. He fell asleep, worn out, after each attack. When awake he was constantly moaning and complaining of his head. On the 24th he had five attacks of tetanoid rigidity early in the morning. They followed rapidly upon one another. The intention-tremor was not quite so marked as when first seen, and the grasp of the right hand was weaker. On the 25th he had no control either over the bladder or the rectum. He died at 11 P.M.

Necropsy.—This was held on Dec. 26th, sixteen hours

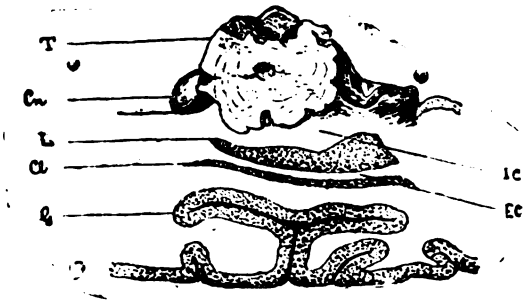


FIG. 1.

Both lateral ventricles were partially opened out, and displayed: T, a tuberculous growth in the left optic thalamus; B, body of left lateral ventricle; Cn, left caudate nucleus; Cn', right caudate nucleus; F, fornix; Cp, choroid plexuses; Ts, tænia semicircularis; CC, corpus callosum; G, cortical grey matter; and Cb, cerebellum. (Diagram one-third natural size.)

after death. Post-mortem rigidity was very marked. There was extensive dorsal hypostasis. I could obtain permission to examine the brain only. The skull-cap was normal. The membranes were congested, but did not show any signs of inflammation. A distinct firm tumour could be felt in the left side of the brain. On opening the left lateral ventricle in the usual way a very considerable quantity of clear serous fluid gushed out. There was no excess of fluid in the right lateral ventricle. The tumour was about the size of a large walnut, and was found to be situated in the left optic thalamus. (See Fig. 1.) A vertico-transverse section through the tumour and left cerebral hemisphere showed that the growth was pressing on the left internal capsule. (See Fig. 2.) The floor of the fourth ventricle presented no signs of pressure, and sections through the medulla and the upper cervical region of the cord appeared normal. Microscopical

FIG. 2.

Vertico-transverse section through the growth and left cerebral hemisphere. T, tumour; IC, internal capsule; EC, external capsule; L, lenticular nucleus; Cl, claustrum; Cn, caudate nucleus; G, cortical grey matter. (Natural size.)

examination of the growth showed it to be undoubtedly tuberculous.

Remarks.—The occurrence of attacks of tetanoid rigidity and the presence of well-marked intention-tremor in the right arm are the principal features of interest in the above case. General tetanic rigidity, constant or paroxysmal, has been met with in several examples of tumour of the pons and of the cerebellum, but, after a careful review of the literature of the subject, I have been unable to find a single instance of tumour of the optic thalamus in which attacks of tetanoid rigidity were noted. The rigidity in this case is exceedingly difficult of explanation; in tumours of the pons or cerebellum it is possibly due to pressure upon the medulla. The localised intention-tremor is of interest as bearing upon the pathology of the intention-tremor seen in disseminated sclerosis. Cases such as the above, where we have a definite and localised lesion in the brain, together with trembling on movement confined to a limb, are especially valuable in helping us to arrive at a true conception of the causation of intention-tremor. The tumour here was pressing on the motor paths in the internal capsule, and it seems to me very probable that the tumour would act in a precisely similar manner to a sclerotic patch in the internal capsule. The nerve fibres would be unequally implicated; the functions of a few would be destroyed, the conducting power of a considerable number would be impaired, while others might escape entirely. The stimuli proceeding from the cortex to certain muscles would, owing to the diminished conducting power of the supplying nerve-fibres, be too few, and as a consequence tremor would result; again, unless the amount of contraction of each of the antagonistic or regulating muscles—which are brought into play in all coördinated movements—is exactly graduated, the balance would be disturbed and incoördination as well as tremor would follow. The implication of the nerve fibres to certain muscles, with escape of the nerve fibres to antagonistic muscles, would bring about this incoördination. Further, it is noteworthy that the tremor in the above case was very slight at the commencement, then gradually got more and more pronounced, until finally, in the later stages of the disease, it again became less marked. It will be observed, also, that as the tremor diminished the paralysis increased. These facts would appear to indicate that the tumour was rapidly increasing in size and destroying in its progress more and more nerve tubules.

Manchester.

SUPERANNUATION ALLOWANCE.—Mr. Edward L. Webb, M.R.C.P. Edin., M.R.C.S. Eng., late Medical Officer of the second district, St. George's, Hanover-square, has been granted a superannuation allowance of £76 per annum.

A CASE SHOWING THE VALUE OF THE LEFT SUPRA-CLAVICULAR ADENOPATHY AS A REVEALING SYMPTOM OF INTRA-ABDOMINAL CANCER; WITH REMARKS.

BY W. ROGER WILLIAMS, F.R.C.S.

SEVERAL cases have now been recorded by Continental observers demonstrating the frequency of the association of enlargement of the left supra-clavicular lymph glands with intra-abdominal malignant disease, to which Troisier[1] first directed attention in 1888. As the subject has escaped notice in this country, notwithstanding its great importance in diagnosis, I think the following case will be of interest.

A married woman aged fifty-six, the mother of six children, having for some months suffered from gradually progressive anæmia and loss of strength, together with failure of appetite, constipation, nausea, and dyspeptic symptoms, in August, 1894, began also to experience pain in the epigastric region, for which she consulted a medical man in September. I first saw her in the following October, when she was markedly anæmic and sallow. The ingestion of solid food caused epigastric pain and after a time nausea and vomiting. She complained of a swelling in the epigastric region, but upon examination no intra-abdominal tumour could be detected. The stomach was not dilated, and there were no signs of obstruction. The liver and spleen seemed normal. There was no history of hæmatemesis or coffee-ground vomit. At this time she was very subject to alternate flushing and pallor of the cheeks and extremities, the fingers often becoming quite dead, as in Raynaud's disease. She was also subject to palpitation of the heart and to occasional syncopal attacks. The urine contained neither sugar nor albumen. Under the influence of rest in the recumbent position, with none but peptonised fluid foods, together with medicines containing belladonna and carbolic acid, the pain subsided, and there was temporary improvement. It soon became obvious, however, that the weakness was increasing; and subsequently nausea, vomiting, and thirst became prominent symptoms. In January, 1895, I saw her again, when she was weaker, paler, and more sallow than on the previous occasion. I was unable to detect any intra-abdominal tumour. The case presented many of the features of pernicious anæmia. She was treated with "bone marrow" and Fowler's solution. This treatment soon had to be given up on account of the pain and vomiting it excited. In April an intra-abdominal tumour was discovered. I saw her again in May, when the emaciation, pallor, and weakness were very great. The vaso-motor symptoms had quite disappeared. Nausea, vomiting, and epigastric pain after food still continued, but there was no hæmatemesis. On abdominal palpation a circumscribed mobile intra-abdominal tumour, about the size of a small turnip, could be felt rather to the right of the median line, midway between the umbilicus and xiphoid. It was dull over its anterior surface. There appeared to be no dilatation of the stomach; the dimensions of the liver and spleen were normal; there was no umbilical retraction. The left supra-clavicular lymph glands, as well as those at the upper part of the axilla, were enlarged and hard; these by interfering with the venous circulation had caused the œdema of the head and forearm. This condition was of rather less than a week's duration. It was evidently due to dissemination of the disease in the glands through the medium of the thoracic duct. The recognition of this symptom completely negatived any exploratory operation. Death ensued about five weeks later, and there was no necropsy. The patient was partially unconscious, with muttering delirium, for some days before the end. The rapid formation of the tumour, its mobility, the considerable size attained, the absence of hæmatemesis, gastric obstruction, hepatic and splenic enlargement, and finally the dissemination by the lymphatics, all seem to indicate a tumour of omental origin—probably a malignant endothelioma.

Remarks.—I will conclude with a brief *résumé* of what is known of the left supra-clavicular adenopathy. The first indication of the affection generally is the enlargement and induration of a single lymph gland, situated behind the posterior border of the lower part of the left sterno-cleido-mastoid muscle. Subsequently adjacent glands become similarly affected; and in the event of life being prolonged they ultimately manifest all the symptoms of malignant disease. This occurs without any of the intervening structures, prevertebral glands, lungs, &c., being invaded. All the different varieties of intra-abdominal malignant disease may cause this affection; but it has hitherto been observed with especial frequency in association with cancer of the uterus. It seems probable that this curious pathological condition is due to reflux of lymph, charged with cancer cells, from the thoracic duct into which the cancer cells find their way from infected lumbar glands. I need hardly insist on the great importance of this manifestation in the diagnosis of obscure intra-abdominal disease and as a contra-indication to operation. The glandular enlargement generally first makes its appearance at a late stage of the abdominal disease; it has, however, been known to have appeared nearly two years before death. Several instances of its occurrence have lately been reported secondary to malignant disease of the testicle.[2] Vidal has met with a case secondary to cancer of the stomach.[3] Spinelli has tabulated thirty-four examples of this condition,[4] and he points out that the glandular enlargement may be accompanied by painful sensations in the region of the neck, shoulder, and arm. Care must be taken not to confuse this adenopathy with the "pseudo-lipome sus-claviculaire" of Verneuil, of which I have given an account elsewhere,[5] the latter affection is simply an overgrowth of the fibro-fatty tissue of the supra-clavicular fossa, both sides being affected; and it is usually met with in well-nourished middle-aged women otherwise in good health.

NOTE ON A RARE FORM OF POST-PARTUM HÆMORRHAGE.

BY SURGEON-CAPTAIN A. W. D. LEAHY, M.D. DURH., F.R.C.S. ENG.,
INDIAN MEDICAL SERVICE.

IN the form of a reprint from the Comptes-Rendus du Congrès Périodique International de Gynécologie et d'Obstétrique Dr. R. A. Gibbons has published a very interesting brochure on what he terms "Tonic Spasm of the body of the Uterus as a cause of Post-partum Hæmorrhage." The condition to which Dr. Gibbons calls attention as a cause of post-partum hæmorrhage is a very rare one, and it is possible that its very occasional occurrence may have led many practical obstetricians to even doubt its existence. That such a condition does occasionally occur causing post-partum hæmorrhage I for one do not doubt, and I can recall two distinct cases of its occurrence in my own practice. The majority of us have been taught, and believe, in the correctness of what the late Professor Matthews Duncan lays down in his writings. Dr. Duncan says: "The proposition I enunciate is that it has never been shown that uterine hæmorrhage of the ordinary post-partum kind ever takes place from the uterus when it is in a state of moderately firm contraction." But the condition of the uterus to which Dr. Gibbons directs attention as a cause of post-partum hæmorrhage is one which its external appearances would lead one to believe was a state of moderately firm contraction, but which internal examination shows to be one of tonic spasm of its walls. The two cases to which I have referred as having occurred in my practice presented themselves at an interval of fourteen years. The first I met with during my period of residence as obstetrical officer to the Charing-cross Hospital, London. The second occurred to me here in Calcutta three years ago. They were curiously alike, and as they may prove of some interest to my professional brethren I append short notes of each.

CASE 1.—A woman aged twenty-seven, married seven

Digitized by Google

years, multipara, was attended by me in January, 1878. The patient was a small, anæmic, nervous woman, and informed me she had suffered from severe flooding after each of her three previous labours. This note was made at the time of her taking out her ticket from hospital. Her father was an epileptic, but she herself had never had a fit. She was an only child. Her labour commenced on the 13th at 6 P.M.; the os was fully dilated at 10 P.M., and the second stage was over at 2 A.M. There was nothing abnormal in her labour, but, bearing in mind her previous experiences, a considerable amount of care was given to the third stage, and after expulsion of the placenta the uterus was grasped and kneaded. It contracted well, was fairly hard, but continued large, and felt somewhat irregular. Then to my astonishment hæmorrhage set in. The bleeding was profuse and in gushes. The patient quickly became collapsed, her pulse failed, her skin became moist and clammy, and she fainted. During the hæmorrhage I followed the usual course of treatment, introduction of the hand into the uterus, clearing out its contained blood, the injection of hot and of iced water, and the placing of ice within the uterus, but these remedies failed. The bleeding continued in spite of the uterus being grasped both externally and internally, and I noted that its walls were hard. The patient I believed to be on the verge of death, and as she fainted I felt the walls of the uterus first relax and then rapidly and regularly contract, forcing my hand from within its cavity into the vagina. The contraction was sustained and the woman recovered, but was weak for weeks afterwards.

CASE 2.—A woman aged thirty-two, married four years, multipara, was confined on Aug. 9th, 1892. After each of her two previous labours she had nearly died of post-partum hæmorrhage. She was a fair, delicate-looking woman of an extremely nervous disposition, and looked forward with great dread to the ending of her present pregnancy. She was attended by Dr. Harvey in her first labour and by Mr. Joubert in her second. In this case, again, the labour was in every way perfectly normal. The first stage was of average duration; the second somewhat rapid. After the end of the second stage a large dose of ergot was administered and the placenta expressed by Credé's method fifteen minutes after the birth of the child. While my hand was on the abdomen grasping the uterus I felt it become softer, enlarge, and then harden again. The organ was irregular in shape, and hæmorrhage at once declared itself. The routine course of treatment was pursued. Hot and iced water was used internally. Ergotinine was injected hypodermically. The interior of the uterus was irrigated with ferric chloride and water. The uterus was grasped between the hands, one within its cavity and the other upon the abdomen, but the hæmorrhage continued. The patient was pulseless, with sighing respiration, complained of noises in her ears, blindness, and rapidly became unconscious. As her consciousness left her I felt the walls of the uterus soften, and this softening was followed by equable and firm contraction which drove my hand down into the vagina. The contraction persisted, but the hæmorrhage ceased. The patient recovered, but for weeks she was extremely feeble and suffered much from fever.

This, shortly, is an account of the only two cases I have met with which appear to me to accurately fit the condition described by Dr. Gibbons—viz., "persistent tonic spasm of the walls of the body of the uterus causing post-partum hæmorrhage." Such cases appear, as a rule, to present the following points in common: (1) the patients are usually neurotics; (2) successive labours in the same patient are always attended by post-partum hæmorrhage; (3) the cases are of rare occurrence; and (4) the hæmorrhage resists ordinary attempts to control it, and its cessation is brought about by syncope with consequent relaxation of the spasm affecting the uterine wall and subsequent contraction. Perhaps, after all, in these cases the etiology is not of such importance as the treatment, and it does not matter very much whether we include them under the heading of "contraction without completeness of retraction" or ascribe them to apolarity or tetany of the body of the uterus. Still, if the view set forth by Dr. Gibbons is correct, if these cases are due to a real spasm affecting the body of the uterus, then, I think, we must admit the value of his view as indicating a line of treatment to be adopted in such cases. In his brochure Dr. Gibbons logically follows out his view of the etiology of these cases by recommending the administration of an anæsthetic as the best form of treatment, and if a third case occurs to me in my own practice I shall certainly use chloroform. The clinical and striking point about these cases of post-partum hæmorrhage is that the body of the uterus can be felt above the pubes perfectly hard, but not regularly contracted, and at the same time the existence of an actual cavity within the body of the uterus from which the bleeding occurs is plainly evident. This short note has no pretensions to originality, and my only justification for having written it is that it may be of some use to my professional brethren in calling attention to a rare form of post-partum hæmorrhage, and indicating a possibly successful method of treating it.

WESTMINSTER HOSPITAL.

A CASE OF UNILATERAL TUMOUR OF THE PONS; DEATH; NECROPSY.

(Under the care of Dr. DE HAVILLAND HALL.)

THIS interesting contribution to the literature of the lesions of this region is a very complete one, and is, therefore, of much value. Dr. Starr has written on this subject, describing a case which was under his care, and giving an abstract of twenty-six others which he had collected from various sources. He considers it possible to arrive at a very exact diagnosis of lesions in this region and summarises his conclusions as follows:—"1. If in any case anæsthesia of one side of the face occurs (not due to neuritis of the trigeminus or the cortical lesion) the lesion lies in the medulla or pons, in the outer third of the formatio reticularis. Its position in this part is to be determined by the other symptoms present; for if it is situated high up (cephalad) in the pons it will be on the side opposite to the anæsthesia, and if it is situated lower down (caudad), in the pons or in the medulla, it will be on the same side as the anæsthesia. 2. If in any case anæsthesia of the limbs occurs (not due to cerebral lesion) the lesion lies in the medulla or pons, in the inner two-thirds of the formatio reticularis, and upon the side opposite to the anæsthesia, or in the spinal cord. 3. If one side of the face and the limbs of the opposite side are anæsthetic, the lesion affects the entire lateral extent of the formatio reticularis and lies in the medulla or in the pons, below the point of union of the ascending and descending roots of the fifth nerve. 4. If the face and limbs of the same side are anæsthetic, the lesion lies in the brain at a point higher than the junction of the ascending and descending roots of the fifth nerve in the pons. Its position is then to be determined by other symptoms. It may involve the entire formatio reticularis in the upper pons, or crus cerebri; it may be situated in the posterior part of the internal capsule; it may lie in the centrum ovale, destroying the radiation of sensory fibres from the internal capsule; or it may be in the sensory area of the cortex in which all of these tracts terminate."[1] For the account of this case we are indebted to the medical registrar, Dr. J. Porter Parkinson.

A labourer aged forty-five was admitted to the Westminster Hospital on April 9th, 1895, complaining of headache and paralysis of his face. He was a single man, coming of a long-lived and healthy family. He had small-pox in 1875 and contracted syphilis in 1877, having a chancre on the penis followed by sore-throat and secondary rash, neither of which were very severe, and both disappeared rapidly under treatment, since which time he had been well. There was some history of excess of beer, but not of spirits. His illness commenced in November, 1893, with some pain over the left malar bone, which lasted three months, and nothing fresh

[1] Sajous' Annual of the Universal Medical Sciences, 1894, vol. ii., A 40, Medical Record, New York, 1893.

Digitized by Google

was noticed till April, 1894, when he had violent attacks of headache on the vertex and left side of the head, coming on almost daily and obliging him to cease work; this lasted till the end of May, when he resumed work, but noticed that his mouth was drawn to the right. In August, 1894, he was again seized with a burning pain in the left side of the face, but managed to work till Sept. 1st, 1894, when his left eye became inflamed; he was then treated for a month at the Ophthalmic Hospital, Moorfields, and finally had the eye removed. Early in January, 1895, he had attacks of vomiting coming on about half an hour after food, which recurred for three months and were accompanied by severe headaches, while about this time he noticed soreness of the left side of the mouth, cheek, and tongue. For the last year his speech had been rather defective. At this time the patient was a man of muddy complexion, with grey hair, and arcus senilis; he was rather anæmic and wasted; there were a few pigmented scars on the legs, but none elsewhere. His arteries were tortuous and fibroid; the pulse was normal and regular. He had severe burning headache above the left zygoma, then there was great tenderness to pressure. His mind was clear, though torpid, and he had no giddiness. His speech was thick and blurred, though distinguishable. The left eye had been removed, but the right had no paralysis, and its pupil reacted to light and accommodation; the fundus was normal. There was slight nystagmus on looking to the right. There was paralysis of all the muscles supplied by the left facial nerve, except for slight movements of the eyelids and forehead when the opposite side moved. The whole region supplied by the left trigeminal nerve was completely anæsthetic, and there was also paralysis and wasting of the left temporal and masseter muscles and apparantly also of the external pterygoid, for when the mouth opened the chin deviated to the left. The skin of the face was rather glossy on the left side, but there was no loss of hair or other trophic change. There was no loss of hearing, smell, or taste on either side. The left vocal cord lay in the cadaveric position, and did not move on articulation; the uvula was drawn to the right, and the arch of the soft palate relaxed on the left, with diminished palatal reflex. There was no paralysis or wasting of the tongue, which was protruded straight forward, but he complained of great soreness on its left side and toothache on the same side. The movements were good in the head and neck. The grasp was slightly less on the right side, and there were increased tendon reflexes in both arms, but no sensory or motor changes. The gait was rather weak and stiff; there was no weakness of the legs, but the knee-jerks were abnormally active, and ankle-clonus could be obtained. There was no affection of the bladder or rectum. There was nothing abnormal in the chest or abdomen, except that the liver was slightly enlarged. The urine was of sp. gr. 1008 and neutral. It contained no albumen or sugar. There was a slight deficit of urates. The patient was given a mixture containing mercury and iodide of potassium, but his headache and malaise continued till April 25th, when he began to have difficulty in swallowing; this improved in a few days, but returned, till finally an attempt to swallow produced choking fits and rejection of the liquid food, so that a catheter had to be used for feeding. On May 7th there was some loss of sensibility to heat and cold in the right arm and leg, and a week later he began to lose power in this side. The choking fits returned independently of food, and he occasionally coughed up a mucoid expectoration. There were detected signs of bronchitis and broncho-pneumonia at the base of the right lung, and the temperature, which previously had been normal, rose to 101·6° F., to drop next day to normal. These fits of choking increased in frequency and exhausted the patient, who was already very weak from the slight amount of nourishment he was able to swallow, till he died on May 17th, about six weeks after his admission. At the necropsy, made by Dr. Hebb, the dura mater was found to be non-adherent to the brain, except over the left lobe of the cerebellum, and for about an inch in the middle of the third left temporo-sphenoidal convolution, where it was firmly attached, and the subjacent cortex was atrophied. The inner wall of the straight sinus was thickened and felt like a solid cord, though the lumen was still patent. In the left cerebellar peduncle, stretching as far as the middle line of the pons, was an elongated gumma measuring 1½ in. by ½ in., firm, gray, and glistening, with central fibro-caseation. The pons was larger than natural and felt boggy. The arteries at the base were normal. The left Gasserian ganglion was atrophied, so that it was about half as large as the right, but there was no thickening around it; the root and divisions of the trigeminal were all thin and atrophied. The left half of the medulla was much atrophied and about three-quarters the size of the right, and there was some wasting of the facial and vagus nerves. There were no changes to be seen in the fresh cord. There was very marked wasting of the intrinsic muscles of the larynx on the left side; also there was well-marked syphilitic aortitis. The lower lobes of both lungs were pneumonic and friable, except the lower part of the right lung, where there was a mass of pigmented fibrous tissue, the superjacent pleura being thickened, white, and opaque—evidently the remains of a syphilitic lesion. The rest of the organs were apparently normal.

Remarks by Dr. J. PORTER PARKINSON.—The diagnosis of this case did not present much difficulty; the paralysis—complete of the trigeminal nerve and partial of the facial nerve—indicated a lesion in the position or neighbourhood of the nucleus of the trigeminal nerve, and when the rightsided hemiplegia became marked this was certain. The evidence of previous syphilis pointed to the lesion being due to a syphilitic lesion, while the absence of involvement of other cranial nerves, such as the auditory nerve, made one suspect the lesion to be in the brain substance. The gradual onset of bulbar symptoms was evidently due to extension of the lesion downwards. The case from the first symptom lasted thirteen months, and it is interesting to note that it began by pain referred to the extremity of the malar twig of the trigeminal nerve. The gumma appeared to press equally on the reticular formation and the pyramidal bundle of the pons, and the loss of sensibility to heat and cold on the right side may have been due to pressure on the former. It would be useless to try to make any deductions from an isolated case but unilateral tumours in this situation are sufficiently infrequent to make it worth while placing each one on record.

WEST HERTS INFIRMARY.

CASE OF PERFORATING GASTRIC ULCER; LAPAROTOMY; DEATH; NECROPSY.

(Under the care of Dr. RUSSELL STEELE.)

THIS case is one of the kind to which special attention has been frequently drawn in the columns of THE LANCET by reason of the great importance of such cases as an addition to our somewhat imperfect knowledge of the subject. The complication which apparently proved fatal, that of the escape of stomach contents through a second ulcer in the posterior wall, is one which need not be in any way regarded as weighing against operation; it is very rare to meet with more than one ulcer. Then, again, it has been calculated that of ulcers on the posterior wall only 2 per cent. perforate, as opposed to 85 per cent. of those situated on the anterior wall. The type of patient appears to have been typical of that recognised as characteristic of the sufferer from gastric ulcer. The promptitude of diagnosis and management of the case were all that could be desired, and we can only regret that the unusual, almost unknown, complication prevented the attainment of the hoped-for success. For the notes of this case we are indebted to Dr. William Martin, house surgeon.

A female patient, unmarried, aged twenty-one years, was admitted to the West Herts Infirmary, Hemel Hempstead, at 9 P.M. on Nov. 17th, 1894, suffering from great shock. She was too ill to go very closely into the history, but the following points were elicited. For about six months she had been troubled with dyspepsia, which had been much worse for about two months. She had severe pain in the "stomach and back" on taking food. The pain, which came on soon after taking anything, was relieved by vomiting. For some time she had vomited after every meal when any attempt was made to take solid food. The pain, although aggravated by ingestion of food, was often felt very severely, quite independent of this, especially in the back. She had never to her knowledge vomited blood or passed any by the bowel. Menstruation began at nineteen years of age, was regular for a short time, but had been absent for six months. On Nov. 17th she was about her ordinary work as a housemaid during the day. She had dinner at 2 P.M., consisting of salt beef and potatoes, but took very little. She had nothing else by the mouth after this. At 5.30 P.M. she was in her room doing her hair, when, as she was stretching her

Digitized by Google

arms up, she suddenly felt intense, agonising pain in the abdomen, and was just able to throw herself on her bed, where she was found soon afterwards almost insensible, and Dr. Russell Steele was sent for. He found her at 6 P.M. lying "curled up" on her side in bed, with all the signs of great shock. She had vomited several times before his arrival, and did so again while he was with her. The vomited matter, all of which was inspected, showed no trace of blood and seemed to consist only of partially digested food and mucus. The presence of a perforating gastric ulcer was suspected. A hypodermic injection of morphine was given, and when the patient had rallied somewhat she was carefully removed to the infirmary, a distance of about 500 yards, and admitted at 9 P.M. On admission, although still greatly collapsed, the patient was beginning to rally. She lay quite still upon her back with the thighs flexed and without complaining of much pain. The abdominal wall was tense from contraction of the muscles, but there was no obvious distension. The movements were very slight, the respiration being almost entirely thoracic. On palpation there was some general tenderness, but distinct pain on pressure was complained of below and to the left of the umbilicus. There was no marked tenderness in the epigastric and left hypochondriac regions. The percussion note was dull at the lower part of the abdomen, but tympanitic in the lumbar regions and elsewhere. The liver dulness was normal. An indistinct sense of fluctuation was made out below the umbilicus. A catheter was passed into the bladder, and a few ounces of quite healthy urine were drawn off. Nothing abnormal was found on rectal or vaginal examination. An exploratory operation was strongly advised, but the relatives would not consent without having a night to think the matter over. The patient's general condition improved somewhat up to 12 midnight, after which she gradually grew worse. Nutrient and stimulating enemata were administered during the night. There was no vomiting after admission, and no passage of motion or flatus by the bowel. At 11 A.M. Mr. F. C. Fisher saw the case in consultation with Dr. Steele. At this time the abdomen was slightly distended, tenderness was more general, a distinct fluctuation wave could be made out, and there was dulness on percussion in the lumbar region on each side. The patient was still in fair condition; the temperature was 99° F. and the pulse 125. The consent of the friends was obtained, and at 12·30 P.M., nineteen hours from the onset of symptoms, she was put under ether by Dr. Hubbard, and Dr. Steele, assisted by Mr. Fisher, opened the abdomen. A median incision was made below the umbilicus midway between it and the pubes. On dividing the peritoneum a considerable quantity of turbid fluid with large flakes of lymph gushed out, and the patient became much collapsed. One pint of normal saline solution was injected into the right median cephalic vein with speedy and obvious benefit. A rapid and careful examination of the vermiform appendix and cæcum as well as the pelvic viscera revealed nothing wrong. The wound was then temporarily closed with a sponge and a median incision made between the ensiform cartilage and the umbilicus. The stomach presented in the wound. At first nothing wrong could be made out, but, on passing the hand over to the left under the costal margin the examining fingers caught in a large rent in the anterior wall. It was impossible to bring the perforation to the wound, so an incision was made at right angles, extending to the left costal margin across the fibres of the rectus muscle. By this means a fair exposure was obtained. The stomach was not washed out, and the edges of the ulcer were not pared. The perforation, which was about the size of a florin, was carefully closed with fine silk sutures after Lembert's method, some difficulty being experienced in introducing those on the extreme left. A second row of sutures was introduced with a hold further back in order to take tension off the main line of suture. A glass drainage-tube was then put into the pelvis through the lower wound to facilitate the flow of fluid, and the whole cavity of the abdomen was carefully and systematically flushed, beginning at the site of the sutured ulcer. The solution used was boiled water containing a drachm of sodium chloride to the pint and at a temperature of 108°, the irrigation being continued until it returned clear. The wounds were then closed, an indiarubber drainage-tube being passed down to the region of the perforation through the outer end of the rectangular incision, and the Keith's tube left in the lower wound. The ordinary dressings were applied. The operation had occupied nearly an hour and a half. At its completion the patient was greatly collapsed. One pint and a half of normal saline fluid was passed into the left median cephalic vein, with distinct but temporary improvement. All the usual remedies for shock were assiduously employed, with the result that the patient completely regained consciousness. She was able to recognise and talk to her friends. During this time she complained of much pain in the back. She, however, gradually sank, and, in spite of all that could be done, died at 5.30 P.M.—three hours and a half from the completion of the operation, and twenty-four hours after the perforation. A partial post-mortem examination was made twenty-four hours after death. There were the usual signs of acute diffuse peritonitis. On dividing the great omentum at its attachment to the lower border of the stomach a quantity of fluid, which seemed to consist of inflammatory exudation and partially-digested food, was found. At first it was not clear where this could come from; but on carefully raising the stomach a second ulcer, about the size of a sixpenny-piece, was found, which had perforated owing to the adhesions which had bound it to the pancreas having given way for the greater part of the circumference of the ulcer. As seen, the stomach wall was still adherent to the pancreas for a short distance along the upper margin of the perforation. The stomach and pancreas were carefully removed. On testing the sutured ulcer it was found to be perfectly watertight. The ulcers were almost exactly opposite to each other, the posterior being a little to the right of the anterior. Both were situated almost vertically below the cardiac orifice and about midway between the lesser and greater curvatures of the stomach.

Remarks by Dr. STEELE.—Although unsuccessful, this case appeared to me to be of particular interest and worthy of publication for the following reasons: 1. Although such extensive ulceration was discovered, the patient had never been so seriously ill as to consult a medical man, and, according to her statements and those of her friends, there had never been hæmatemesis or melæna at any time. 2. The ill-defined nature of the physical signs on admission, the fact of the chief signs on examination pointing to some lesion in the lower part of the abdomen led me, in spite of the history of gastric trouble, to explore this region first. 3. A great point of interest and importance was the presence of another ulcer on the posterior wall of the stomach. I think it probable that the adhesion between it and the pancreas may have been broken down during the necessary manipulations for suturing the ulcer on the anterior wall. It was a matter for regret that permission to operate could not be obtained at an earlier period, although the presence of an undiscovered perforation on the posterior wall of the stomach would have caused a fatal result in any case. In conclusion, I wish to tender my grateful thanks to my colleague, Mr. Fisher, and to Dr. William Martin, my house surgeon, for their valuable assistance, as also to my partner, Dr. Hubbard, who kindly administered the anæsthetic.

Reviews and Notices of Books.

A System of Surgery. Edited by FREDERICK TREVES, F.R.C.S., Surgeon to the London Hospital. Vol. I. With two coloured plates and 463 illustrations. Cassell and Company, Limited, London, Paris, and Melbourne. 1895.

[FIRST NOTICE.]

THE appearance of a new text-book of surgery is, or should be, an important event in medical literature, and the volume before us is a notable addition to the standard works on surgery. The whole work will appear in two volumes, of which only the first has at present been published. This is a handsome large octavo volume of over 1100 pages of text, well printed, copiously illustrated, and presenting an attractive appearance. The publishers are to be heartily congratulated on the way in which their share of the work has been done.

"A System of Surgery" is the work of twenty-five writers, with two exceptions surgeons, who have been well selected from among the acknowledged representatives of the present phase of surgical teaching. The twenty-three surgical authors

Digitized by Google

are general surgeons engaged in the practice and teaching of surgery, and so-called "specialists" are conspicuous by their absence. "The object of this work is to present concisely and with authority an account of the science of surgery as it exists at the present day," and readers of its pages will find in it the best expression of the best teaching of our British medical schools. The coöperation of many writers in producing a single work on surgery is now a well-recognised procedure and seems to be gaining in popularity. It has obvious advantages, and if the writers are well selected and the editor is judicious the merits of the plan far outweigh the disadvantages which result from difference of style and point of view, and from a certain amount of overlapping which cannot possibly be prevented. Having carefully studied the volume before us, we are bound to speak in high praise of it. Mr. Treves shows himself to be an admirable editor, who has wisely allotted the articles among his staff of authors, and in every case the writers show not only a considerable knowledge of the subjects on which they write, but also a particular interest in them. The merit of the different articles varies, of course, but as a whole they attain a very high level of success, and a general uniformity of scope and method of treatment quite equal to those found in any text-book by a single author.

The work is prefaced by an admirable chapter on Surgical Bacteriology from the pen of Dr. Sims Woodhead, written with an easy mastery of the subject and full of practical utility. That a work on surgery should open in this way is a signal proof of the great change that has been wrought in current opinion and teaching by the discovery of pathogenic micro-organisms. The chapters on Inflammation and its Consequences, on Gangrene, and on Wounds and Contusions, by Mr. Watson Cheyne, are an admirable exposition of the latest knowledge and best practice in this department of surgery. It is hardly too much to say that these are the most important chapters in any work on the science of surgery. By far the most important part of surgical pathology is that concerning inflammation and its results, and a knowledge of the healing of wounds, and of the conditions favouring, retarding, and preventing it, underlies all surgical therapeutics. Nowhere will the student find these subjects handled more lucidly and more scientifically than in Mr. Watson Cheyne's articles, and these chapters, together with Dr. Sims Woodhead's, form an altogether admirable introduction to the work. Mr. Lockwood writes on Erysipelas, Pyæmia, Tetanus, and Burns, and his chapter on Tetanus in particular is well up to date. Surgeon-Major Duncan deals with Military Surgery in an article which is concise and clear and shows a very thorough mastery of his subject.

Mr. Makins contributes the chapters on Surgical Diseases due to Microbic Infection and Parasites and on Rickets. Syphilis and Gonorrhœa are discussed by Mr. Jonathan Hutchinson, jun., who also writes on Diseases of the Skin, and in the choice of his subjects as well as in his treatment of them he exhibits the influence of heredity. Mr. J. H. Morgan's brief article on Injuries and Diseases of Lymphatics and Mr. Bowlby's on Injuries and Diseases of Nerves are among the best in the volume.

Mr. J. H. Morgan's is a very carefully written and concise article on Diseases of the Lymphatics and discusses briefly Tuberculous Adenitis, which is dealt with at greater length by Mr. Treves in his article on Tubercle. Some may be inclined to object to this double discussion of a single affection, but it has its advantages when the articles are written by different authors, for the reader has the opportunity of seeing the subject from two points of view. Mr. Bowlby's article on Injuries and Diseases of Nerves is a very admirable one, in which the student will find subjects which are apt to be regarded as difficult and abstruse, dealt with in a clear and concise fashion. This branch of surgery has become of great importance within recent years, not only on account of the introduction of nerve suture and operations for neuralgia, but from the great part that the nervous system is now known to play in diseases of the joints, &c. All these matters are admirably dealt with by Mr. Bowlby. The large and important subject of Tumours is dealt with by Mr. Bland Sutton, whose monograph on that subject and many contributions to our knowledge of certain forms of tumours, especially dermoids and cysts, give him an undeniable claim to be heard. The classification of tumours is simple and comprehensive, and will be highly appreciated by students. This chapter is illustrated by many excellent woodcuts—the subject lends itself to such treatment. The same surgeon deals also with the Diseases of the Jaws, a subject to which he has devoted much attention.

JOURNALS AND REVIEWS.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and W. F. R. WELDON, F.R.S. New Series, No. 148. Vol. XXXVII., Part 4. June, 1895. London: J. and A. Churchill.—The contents of this part are: 1. The Anatomy of Alcyonium Digitatum, by Sydney J. Hickson, M.A., D.Sc., Beyer Professor of Zoology in Owens College, Manchester. Notwithstanding the circumstance that many distinguished naturalists have examined and written upon the structure of the colonies of this animal known as "dead men's fingers," Professor Hickson has been able to discover various new features, which he has described at length and has illustrated by many excellent drawings. He finds that the polypes forming the colonies contract and expand synchronously with tide intervals, or twice in twenty-four hours. The process of sexual reproduction occurs on our southern coasts during the months of December and January, and the colonies are invariably dicœcious. The ova are shot out of the mouth singly at considerable intervals, and the gonads are as long as nine months in reaching maturity. Professor Hickson has satisfied himself that the ectoderm is not ciliated. For the details of the histology of the animal we must refer to the original. A note is appended to Professor Hickson's paper by W. Langdon Brown, B.A., on the Chemical Constitution of the Mesoglœa of Alcyonium Digitatum. It appears to be of the nature of mucin, and at all events does not contain gelatine or nucleo-albumen. The principal article in the part is a Study of Metamerism, by T. H. Morgan, Ph.D., Associate-Professor of Biology, Bryn Mawr College, U.S.A., with four plates. In this article Dr. Morgan takes up the subject of irregularities in the serial repetition of the rings of annelids, which, he points out, possess considerable importance in the interpretation of the general problem of metamerism. He gives the typical forms of modification, the variation in the position of the reproductive organs, the abnormalities in front of or including the fifteenth metamere, the study of embryos, the abnormalities at the posterior end, the modifications of internal structures, the modifications in antennæ of arthropods, the abnormal metamerism of locusts, a study of colour-bands in echinoderms, and regeneration in earthworms. The article is one of considerable research and much interest. The last memoir in this part of the journal is by Edwin S. Goodrich, F.L.S., assistant to the Linacre Professor of Comparative Anatomy, Oxford, and deals with the cælom, genital ducts, and nephridia in Planarians, rotifera, entoprocta, mollusca, and the higher animals. Many illustrations accompany the paper.

The Journal of Physiology. Edited by MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. Vol. XVIII., No. 3. London: C. J. Clay and Sons. July, 1895.—This part contains six articles: 1. On the Escape of the Heart from Vagus Inhibition, with four figures in the text; by Theodore Hough. 2. The Relation of the Action of Carbonic Oxide

Digitized by Google

to Oxygen Tension, with two figures in the text; by John Haldane. 3. On the Exchange of Blood Gases in Brain and Muscle during States of Rest and Activity; by Leonard Hill and D. N. Nabarro. 4. The Physiological Effects of Extracts of the Suprarenal Capsules, with twenty-six figures in the text; by George Oliver and E. A. Schäfer. 5. On the Physiological Action of Extracts of Pituitary Body and certain other Glandular Organs; by George Oliver and E. A. Schäfer. 6. Note on Regeneration of Præganglionic Fibres of the Sympathetic; by J. N. Langley. The number also includes the Proceedings of the Physiological Society.

THE LANCET LABORATORY.

"VITALIA" MEAT JUICE.

(THE VITALIA COMPANY, WALTHAM-BUILDINGS, 1, HOLBORN-CIRCUS, E.C.)

WE have not examined a more powerful meat "expression" than that which significantly enough is called "Vitalia." It is free from objectionable preservatives, keeps perfectly fresh for a reasonably long time, and has a pleasant, agreeable flavour characteristic of the freshly expressed juice of uncooked meat. It turns quite solid on heating, a fact due to its richness in coagulable albumen, which amounts to no less than 21 per cent., while the uncoagulable matters amount to 12·50 per cent., leaving a difference of 66·50 per cent. which may be regarded as water. The mineral matter was equal to 6·52 per cent. and contained phosphates and iron proportional to the excellent quantity of meat principles present. These results make evident its potent properties as a restorative, stimulant, and nutrient.

OBESITY BISCUITS.

(CALLARD AND CO., 65, REGENT-STREET, S.W.)

The elements of our common diet contributing most to the formation of fat have been carefully excluded from these biscuits, which have therefore been prepared without starch, sugar, or butter. Our analysis is in perfect accordance with this statement, since we found ether extracted no butter fat and boiling water practically no starch or sugar. In spite of this depletion the biscuits are of unquestionable food value, as we also found that they contained slightly over 3 per cent. of nitrogen, which adopting the factor 6·25 would represent a fourth part of their weight as consisting of the so-called albuminoids. It only remains to add that their palatability is remarkable considering the entire absence of the substances already alluded to.

(1) SYRUP CINCHONÆ HYDROBROM; (2) SYRUP CINCHONÆ ET FERRI HYDROBROM.

(FLETCHER, FLETCHER, AND CO., HOLLOWAY, N.)

These preparations deserve praise because each is a successful and elegant pharmaceutical combination of well-known valuable therapeutic agents. The first is a perfectly bright, clear, reddish-brown liquid and quite permanent in composition, though it contains the whole of the important principles, together with the aromatic constituents of selected cinchona bark, associated, moreover, with bromine. Its administration affords all the advantages in regard to the tonic properties of the bark, and the success of the combination is such, it is said, as to obviate the disagreeable effects (headache and gastric disturbance) which not infrequently follow the administration of ordinary tinctures. The syrup cinchonæ et ferri hydrobrom is equally satisfactory. It is, as might be expected, slightly darker than the former compound, but just as perfectly clear and bright. These improvements, which Messrs. Fletcher have most satisfactorily effected, are of real importance, as by ensuring greater certainty of action they are calculated to give increased confidence in the use of one of the most valuable tonic combinations which the Pharmacopœia affords. It should be added that the advantages of these standard and reliable preparations of cinchona are secured also in the agreeable form of an excellent wine which is called "Vibrona."

CONDAL WATER.

(CONDAL WATER CO., LIMITED, LAMBETH-HILL, E.C.)

We have recently confirmed in our laboratory the published analysis of this natural aperient mineral water. It is bottled at the Rubinat spring in Spain, and is highly mineralised with sulphates, with the important distinguishing feature, however, that it contains a proportion of sodium sulphate largely in excess of the corresponding magnesium salt. Thus the sulphate of soda amounts to 45 grammes per litre, and the magnesium sulphate to a little over 3 grammes per litre. On this account probably the taste of the water is only slightly bitter and is soft and saline. Since the sodium salt as regarded at present has certain advantages over magnesium sulphate in that it has less tendency to produce irritation in the intestinal tract, Condal Water may be given with confidence, and especially, it would appear, in certain idiosyncratic cases.

OPHIR WINE.

(P. B. BURGOYNE AND CO., 6, DOWGATE-HILL, CANNON-STREET, E.C.)

The vineyard on Mount Ophir whence this wine derives its name is situated at a considerable elevation in Rutherglen, in Victoria Colony, Australia. The soil is rich in ironstone, from which it is concluded that the wine produced there becomes of a ferruginous character. Our analysis of it was as follows: Alcohol, by weight, 13·85 per cent.; by volume, 17·08 per cent.; proof spirit, 29·92 per cent.; extractives, 3·29 per cent.; sugar, 0·28 per cent.; total acidity, reckoned as tartaric acid, 0·48 per cent. It is a rich, fruity, and robust red wine, containing, as claimed, a definite quantity of iron in solution, the actual amount of which, according to our analysis, was equal to one-seventh of a grain per pint, or, broadly, one grain per gallon. Considering the composition and character of grape constituents, the iron is undoubtedly present in an organic form and favourable for absorption and appropriation in the system. The wine probably serves, therefore, as an effective and agreeable tonic, referable partly to the important quantity of iron contained in it and partly to its richness in fruity elements. Whilst it is practically free from any acidity it contains also only a trifling quantity of sugary constituents. Its flavour is peculiar, but full and round. It does not obviously belong to the class of light table wines, but merits a foremost place amongst those vigorous wines of the Burgundy type, which may be taken in moderate quantity with advantage by those requiring improvement of tone and vigour.

NEW TABLOIDS.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, E.C.)

Some useful additions have recently been made to the large number of medicaments now embracing most of the preparations of the Pharmacopœia which are procurable in the form of tabloids. "Gregory's Powder" tabloids contain a proportion of sodium bicarbonate in the place of magnesium carbonate, the use of the sodium salt being supposed to give a more beneficial result than ordinary compound rhubarb powder. Tabloids of ipecacuanha wine (five minims) afford a convenient means of administering ipecacuanha wine as an expectorant, a single tabloid slowly dissolved on the tongue producing the well-known effect of the wine. The portability in particular of this preparation is an obvious advantage. The composition of nasal tabloids is based upon a formula suggested by Dr. Carl Seiler for the preparation of a solution which is used with good results as a douche for the nostrils or as a gargle in nasal or pharyngeal catarrh. It is an alkaline and powerfully antiseptic compound, containing

Digitized by Google

the bicarbonates, borates, benzoates, and salicylates of soda, with eucalyptus, thymol, menthol, and oil of gaultheria. The solution, as may be gathered, possesses a very agreeable aromatic smell, and it is said to be effective also as a mouth wash in fungoid formations or for mercurial stomatitis.

EUCALYPTUS SANITAS SOAP.

(THE SANITAS COMPANY, LIMITED, LETCHFORD'S-BUILDINGS, THREE COLT-LANE, BETHNAL GREEN, E.)

On analysing this soap we found that the ingredients are well adjusted in accordance with the delicate requirements of a toilet soap; it contains no free alkali or other ingredients injurious to the skin. Little else in favour of the preparation considered merely as a soap need be added. In the present case, however, the soap is pleasantly medicated with "sanitas" and eucalyptus, both of which possess hygienic properties. It is, further, an economical soap, since we found that it contains only a minimum of moisture.

(1) FINE CUT, AND (2) MEDIUM OATMEAL.

(W. DUKE, "ANGUS" OATMEAL AND BARLEY MILLS, KIRRIEMUIR.)

Samples of both coarsely and finely ground oatmeal were submitted to us, which are described as being prepared by the "newest and most approved milling machinery." However this may be, both products possess a fine, rich flavour characteristic of a superior product, while the process to which the grains have been submitted undoubtedly improves the digestive qualities and flavour of the meal, making it generally more suitable for dietetic requirements.

CHAMPAGNE VITALITÉ: VIN DIGESTIF.

(AYALA: HENRI LAURANCE ET CIE. LONDON: MAXTON AND CO., 35, WALBROOK, E.C.)

An evidently choice and dry wine containing an addition of pepsin which we found to exhibit distinct digestive action upon egg-albumen. Thus its digestive action was readily ascertained by slightly acidulating the diluted champagne with hydrochloric acid, and observing the effect of this liquid, at blood heat, upon thin slices of hard-boiled white of egg. The action was at first slow, but subsequently (in a few hours) the white of egg was quite dissolved. The composition of the wine, according to our analysis, was as follows: Alcohol, by weight, 11·08 per cent.; by volume, 13·71 per cent.; proof spirit, 24·03 per cent.; extractives, 2·70 per cent.; mineral matter, 0·30 per cent.; sugar, 1·50 per cent.; total acidity, reckoned as tartaric acid, 1·07 per cent. Apart, therefore, from presenting the generous qualities of a superior champagne, this wine doubtless affords also the additional and important advantage of serving as a mild digestive.

THE A.H. DISINFECTANT (LIQUOR CRESOLI SAPONATUS).

(A. HELBING, 25, BOUVERIE-STREET, FLEET-STREET, E.C.)

Liquor cresoli saponatus is a powerful antiseptic compound consisting of a soapy solution of creosol, which in crude coal tar is associated with carbolic acid, but from which it is easily separated by distillation. This preparation offers distinct advantages, since while it is undoubtedly a strong bactericide it is practically non-poisonous, and the presence of a noteworthy proportion of soap renders it bland, non-corrosive, and non-irritant.

CONFECTIONS MADE IN SILVER PANS.

(G. PEARSON, NEWCASTLE-CHAMBERS, NOTTINGHAM.)

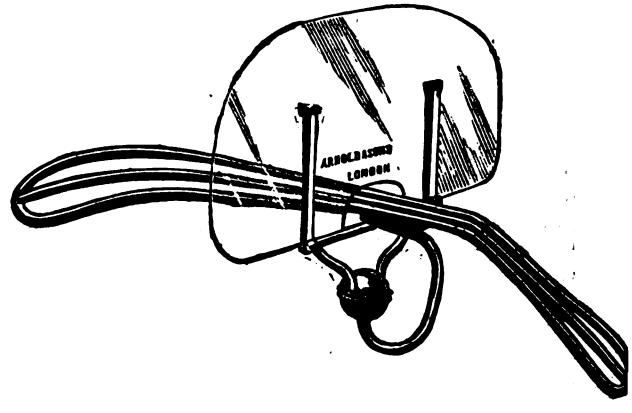
In the preparation of any substance destined for human consumption we are always glad to record the fact of measures being taken to ensure the utmost possible purity of the product, especially in regard to the possibility of contamination with metallic or other injurious substances. Such is the case with some specimens of butter-scotch and almond rock of the above manufacturer which we have recently received and which are made in silver pans. In view of these admirable precautions it could only be expected that the best and purest ingredients would be employed in their preparation. The excellent flavour of the sweetmeats referred to afforded confirmatory evidence on this point.

LACTOPEPTINE TABLETS.

(J. M. RICHARDS, 46, HOLBORN-VIADUCT, E.C.)

The composition of "Lactopeptine" tablets is based upon the following formula of lactopeptine powder: Sugar of milk, 40 oz.; pepsin, 8 oz.; pancreatine, 6 oz.; diastase, 4 drachms; lactic acid, 5 fluid drachms; and hydrochloric acid, 5 fluid drachms. We have proved its digestive powers by observing its proteolytic action upon egg albumen. Each tablet contains 5 grains of lactopeptine, the uses and value of which are obvious from the formula.

PURITAS DRY SOAP.



(THE DIANA MANUFACTURING SYNDICATE, LIMITED, 15, BLOSSOM-STREET, BISHOPSGATE, E.)

Whilst admitting that this soap is probably of service for drastic cleansing operations, we do not understand why it should possess any claim to special disinfecting properties. It is a dry powder, having a slight aromatic smell and containing free alkali in the shape of carbonate of soda.

New Inventions.

A SHIELD FOR PROTECTING THE FACE DURING APPLICATIONS TO THE THROAT IN DIPHTHERIA.

I VENTURE to bring to the notice of the profession an appliance which I have designed for the protection of the face during examination of, and application of remedies to, the throat in cases of diphtheria &c. Having myself contracted diphtheria on two occasions from contact with matter coughed out whilst examining in the usual way, and knowing that such accidents are not uncommon, it occurred to me to interpose a shield of some transparent material, and I found that mica or talc answered the purpose exceedingly well, and I am now able in cases of this description to make a careful

Tongue depressor with shield.

examination in comfort. The metal tongue depressor is well curved and has a detachable carrier; the face shield is of mica, the carrier being connected with a ball and socket joint, and sliding backwards and forwards on a bar or under-surface of the depressor, so that the shield is freely movable and can be used for adults or children. By removing the carrier the depressor can be used in the ordinary way. Being of mica the shield is very light, transparent, and easily kept clean. To prevent clouding in cold weather it may be warmed before use. When artificial illumination through the shield is required I use a candle, lamp, or Mackenzie's laryngoscopic mirror. Messrs. Arnold and Sons, of West Smithfield, are the makers.

THE LANCET.

LONDON: SATURDAY, AUGUST 3, 1895.

IT was a happy thought of the President of the British Medical Association, Sir J. RUSSELL REYNOLDS, to place in the very front of his interesting address the corresponding address delivered twenty-two years ago by the ever to be lamented Dr. PARKES, and to contrast the state of medicine in 1873 with its state in 1895. All who remember that admirable man know how he loved every branch of medicine, and with what insight he saw into the very depths of the subject as it presented itself then. And no one will peruse the address which he delivered to the Association when it last met in London without being charmed with its spirit, astounded by the range of its knowledge, and impressed with the prospects of medicine. Yet there was one passage at least which justifies Sir J. RUSSELL REYNOLDS's reflection as to the bewilderment and perplexity which his departed friend would experience were he now to "revisit Netley, or his still older haunt, University College, and see his house surgeon feeding a patient on 'sweetbreads' or injecting thyroid extract for the cure of myxœdema." After alluding to the two great discoveries which at the beginning of his studies had hardly yet made their full impression on medical practice—viz., RICHARD BRIGHT'S recognition of albuminuria and LAENNEC'S application of the ear to discover the normal and abnormal action of the heart and lungs—Dr. PARKES said: "These two discoveries stand high above all that has followed, nor is it likely that equal advances will be made in this century." It would not be fair to bind a generous and hopeful mind like Dr. PARKES's to a piece of prophecy which even such minds do well to avoid. But it cannot be doubted that if he had lived to hear his friend's address of 1895, recounting the advances of medicine in the last third of the nineteenth century, he would have admitted that in promise, if not in actual and immediate interest, the discoveries and advances of the later period are in no way unworthy of comparison with those which he so justly magnified in the first third. Sir J. RUSSELL REYNOLDS'S account of recent advances which give a character to the epoch in detail will be read with attention by our readers. But in one sentence he seizes upon the really interesting feature common to them all. The sentence is this: "What my object in this address is mainly concerned with is to draw your attention to that which seems to me to be the most striking fact of modern physiological, pathological, and therapeutical research—viz., the power of 'living' things for both good and evil in the conservation of health and in the prevention or cure of disease." Sir J. RUSSELL REYNOLDS in this one sentence hits off the great advance of medicine. In the time of Dr. PARKES no doubt the foundation of all biological, or rather bacteriological, work had been laid in the discovery of the bacillus anthracis (1849) by POLLENDER. But its fruitfulness had not yet been gauged, and a long interval was to elapse between the foundation and the superstructure. Not to mention others, how rich has been the fruit of that seed which has led to the discovery of the actinomycosis (1877), of the bacillus lepræ (1879), the parasite of ague (1880), the bacillus of tubercle (1882), of glanders (1882), of diphtheria (1884), and of tetanus (1884). With such revelations of the relation of "living" things to the great groups of disease which make up so much of the misery of the world, and of means whereby they can be controlled or destroyed, he President might well say that "our failures in the last twenty years are small in comparison with our successes, and that nothing that has happened in this time is to be compared in importance with the new revelations that have been made of the potency and the prepotency of life—the power of life in life—in health, in disease, and in its treatment." There is one broad distinction which seems to differentiate the significance of the discoveries which figured so largely in the mind of Dr. PARKES from those which strike us so much since. They had reference rather to processes of degeneration slow in their progress, and possibly produced rather by non-living substances; these have reference for the most part to gravely acute diseases which act quickly and often end fatally, and which await, with one or two exceptions, that greater discovery still, the discovery of a medicine, organic or inorganic in its nature, which shall destroy them before they have destroyed the body in which they commit their ravages. This, indeed, is the great achievement for which men wait and which is needed to complete the fame of medicine. There are already indications of this great consummation. We only want a germicide for other bacilli which will act on them as quinine acts on LAVERAN'S bodies, or an antitoxin which will act on specific poisons as PASTEUR'S virus does on those threatened with rabies, or as vaccinia does on those exposed to small-pox. This is all, and medicine will enter on a new sphere of usefulness and of glory. But though this is all, it is much. Its realisation may well take the remaining years of the century. Meantime, the public is in danger of expecting too eagerly and confidently this consummation, and not the least duty of the profession to the public in its present mood is to moderate its eagerness by being severely critical and almost sceptical in its own mood. We see with pleasure that this is its attitude towards one antitoxin at the present moment of surpassing interest. The President of the British Medical Association was not less discerning in his allusion to the advantage accruing to medicine of late years from deeper knowledge of the functions of organs some of which had been thought altogether useless and superfluous, and of the interdependence of tissues and organs on each other of which the therapeutics of myxœdema supply the most striking illustration.

We must bring our notice of this address to a close. It will command respect from the fundamental thought which runs through it all—the respect for life as for something as mysterious in its virtues as it is in its nature. A physician never appears to greater advantage than when he thus recognises the "living" principle as that with which he has to reckon in disease, either for its causation or its cure. It was fitting that at the close of

Digitized by Google

such an address Sir J. RUSSELL REYNOLDS should indulge in a more general view of life under the head of professional life and social environment. He must be strangely out of place who can be in the profession and not realise its obligations to the State and to society as well as to his medical brethren; and equally must he be unworthy of his profession who can look without concern on the absence of reverence in society and in much of our current literature for all that constitutes the religious element of life, for that which is the groundwork of "social" propriety, and for the constituted order of relative dignity in family life. In this time of "new women" and newer men there are, perhaps, a few medical men who think themselves well employed in giving sanction to such innovations; but they have no countenance from that distinguished member of our profession who is at the present moment the President of the Royal College of Physicians and of the British Medical Association.

FEW themes are more interesting than that which Sir W. BROADBENT selected for his address to the members of the British Medical Association, whilst to have successfully presented a clear and vivid picture of the history of medicine within the time allotted to the delivery of such an address is a matter upon which both orator and audience may be congratulated. The sketch thus given was bold in outline, yet comprehensive and for its purpose sufficient. Nothing that can be deemed essential was omitted, so that as the speaker unfolded the roll it was not difficult to trace with him the stages of thought and practice which have in turn marked the progress of the medical art. The distinction which was made in the opening of the address between the art of healing and its science is one which as knowledge grows will come to be less sharply defined, for it is year by year more apparent that the whole rationale of medicine and of therapeutics is based on scientific foundations. It is doubtless true that so far the art has been in advance of the science; but it is also true, as indeed is apparent from the tenor of this address itself, that scientific medicine, which is still in its infancy, is destined to become conterminous with the practical art. That this is the correct interpretation of the position assumed by Sir W. BROADBENT himself is shown by his significant aphorism that, given certain attributes of acumen and character, "the best physiologist will make the best pathologist, and the best pathologist the best physician." Admitting this, it is surely a wholesome and useful thing to dwell at times upon the past, when physiology and pathology were unknown, and to note with mingled feelings of admiration and humility the position attained by our forerunners in medicine.

The truly remarkable powers of observation and insight possessed by such fathers of medicine as HIPPOCRATES and GALEN, which were illustrated with terseness and force in this address, and the memorable works which have happily been handed down from them, were of such an order that it is not surprising that they guided the practice and theory of medicine for centuries. The dominating influence of Hippocratic doctrine—of which the essence was humoralism—was apparent even to the days of SYDENHAM, whom we claim, and not unjustly, as our pioneer in exact clinical observation. With the name of SYDENHAM Sir W. BROADBENT associated those of BOERHAVE and his pupil VAN SWIETEN, who undoubtedly possessed a wide influence upon medical learning. These three men have left behind them writings which open up a new era in the medical art, for they may be said to have been amongst the first to break through old traditions and to have the courage and independence to seek in bedside observation for an interpretation of the nature of disease. It is singular that from this time for more than a century medical thought should have been swayed in more than one direction by fanciful hypotheses and systems, the effect of which was not to advance medicine, but to hold it in thraldom quite as stringent and narrow as in mediæval times—and this notwithstanding the advancing knowledge of the structure and functions of the body that dates from the epoch of HARVEY. However, these perturbations in doctrine were but the precursors of the more stable and reasonable interpretation of natural phenomena which came to light at the close of the eighteenth century.

In the marvellous advances made in every department of science during the present century medicine has taken a large part. Many a cherished doctrine has been swept aside, and new conceptions of disease and its environment have been framed, so that within living memory the pathological aspect has been wholly changed. In whatever direction we look, whether it be in physiology or in pathology or in therapeutics, we see not merely a revolution of opinion and thought, but almost an entire recasting of our attitude in the investigation of the problems of normal and discovered function. Science has entered into possession of the kingdom where imagination and fancy were once enthroned, but she has many a campaign yet to make and many a battle to win before the victory is wholly gained.

It is needless to particularise here the special lines of the advance of science upon the Hippocratic strongholds—they are patent to all; and if any illustration were needed it would be found in the subjects discussed at congresses such as this which, as we write, is proceeding in the metropolis. For whilst we reverence the past and the master minds that first showed us the paths by which we now travel, we press forward through further conquest of ignorance and superstition towards the goal that every faithful follower of medicine has had in view—the attainment of truth and the dispersion of error for the benefit of suffering humanity.

THE present is not the first occasion upon which Mr. HUTCHINSON has been requisitioned to deliver a vicarious address in Surgery at the annual meeting of the British Medical Association. The address this year had originally been entrusted to Mr. ARTHUR DURHAM, and in feeling and felicitous terms Mr. HUTCHINSON alluded to the early death which had robbed him of a much-loved friend, surgical science of one of its most talented and genial cultivators, and the Association of the pleasure of listening to a surgical oration from a very able speaker. From Mr. DURHAM Mr. HUTCHINSON glanced back to one of Mr. DURHAM'S many distinguished

Digitized by Google

predecessors, SAMUEL SHARP, who published in 1750 "A Critical Inquiry into the Present State of Surgery," and SHARP'S summary suggested a surgical comparison between the present and the past, between the time when PERCIVAL POTT was in his prime and JOHN HUNTER a young man, and the year of grace A.D. 1895. "SHARP'S thirteen chapters concern hernia, lithotomy, amputations, concussion of the brain, tumours of the gall-bladder, extirpation of the tonsils, hydrocele, and a few others. What a contrast is presented with the almost limitless multiplicity of the subjects which in the present day claim the attention of his successors!" And SHARP'S general experience of the major operations which were then performed, mainly consisting of excision of tumours, amputations, and cutting for stone, may be gathered from his praise of extirpation of the tonsils as an operation "neither dreadful in the doing nor melancholy in the event." Looking forward another half century, when the life of HUNTER, the father of scientific surgery, had passed, Mr. HUTCHINSON paused over M. ROUX, the distinguished surgeon of La Charité, who published the result of his observation during a month spent in London in the diligent investigation of English surgery. ROUX, who had seen LAWRENCE, BRODIE, and BELL operate, considered the London operators skilful but terribly slow, one of the best taking twenty minutes over a circular amputation which any Paris surgeon would have finished in five. Much inferior in England, too, was the attention given to the management of fractures to that in Paris. Incidentally Mr. HUTCHINSON praises ROUX for his sagacity in pointing out the weak points in the management of the Royal College of Surgeons, an institution for the advancement of surgery—viz., the devotion of the best part of the museum space to comparative anatomy. Collections of skulls and skeletons—"a Golgotha anthropology"—and the formation of a vast anatomical reading-room for students make this fault more conspicuous now than ever. Mr. HUTCHINSON sighs very naturally for a museum of clinical surgery. On the other hand, ROUX'S condemnation of the special institutions hen appearing for the treatment of eye diseases was itself condemned by the results of the ophthalmic practice in ROUX'S own general hospital, which Mr. HUTCHINSON witnessed many years after the date of ROUX'S visit. "I then saw," he says, "cases of extraction of cataract treated in the open ward and by the hand of the general surgeon, and I saw eye after eye lost by suppuration."

Perhaps the most interesting part of Mr. HUTCHINSON'S interesting and suggestive address is the chapter from his own personal professional history, which commenced when he became junior coadjutor to SPENCER WELLS, the then editor of the *Medical Times and Gazette*, and, in pursuance of a scheme initiated by Mr. WELLS, visited the various London hospitals for the purpose of recording the results of their operative surgery. The formation of Mr. HUTCHINSON'S opinions on various operations and his stores of clinical surgical knowledge had their foundations laid at that time. Every day he was in the operating theatre of one or more hospitals, and in constant confidential communication with the hospital surgeons of the day, and he became cognisant of details which it was not permissible to put into print. Of two operations Mr. HUTCHINSON'S early impressions were extremely unfavourable. At a time when fourteen cases of ovariotomy in succession at different institutions terminated fatally, and Mr. BAKER BROWN was threatened by the coroner with an inquest on the next case dying after the operation, it was no wonder that both Mr. WELLS and Mr. HUTCHINSON regarded the procedure as not much removed from manslaughter, and yet both in their several degrees and separate spheres became pioneers of an operation which is generally regarded as almost the greatest of modern surgical achievements. Similarly, with regard to lithotrity, the hospital practice witnessed by Mr. HUTCHINSON showed a not inconsiderable mortality after the operation, prolonged and often frequently repeated suffering, and the stone after all not entirely eliminated. It is not surprising that Mr. HUTCHINSON, himself a skilful lithotomist, should have exhibited a marked preference during his whole hospital career for lithotomy, and that he has only been converted to lithotrity with regret by witnessing the remarkable success which attends in skilled hands the more recently introduced practice of lithotrity in the shape of the litholapaxy of BIGELOW. Everyone must sympathise with Mr. HUTCHINSON in his disappointment concerning the fate of the clamp which he had improved, and which held its ground for a decennium in the treatment of the ovarian pedicle. At the time of its introduction the clamp so modified was regarded as a great advance and improvement, and the extra-peritoneal method of disposing of the pedicle triumphed over the now almost universally adopted intra-peritoneal plan. Mr. HUTCHINSON, like many other inventors and original workers, hoped that he had placed a permanent stone in the edifice of surgical progress. Yet he has lived to find the clamp discarded and occasionally jeered at as the greatest obstacle to the improvement of the operation and the diminution in its mortality, which existed during the time that it was in vogue. But such denunciations are altogether unjust, and Mr. HUTCHINSON may take comfort from the fact that, as Dr. SKENE KEITH informs us, "Dr. KEITH'S mortality with his first clamp cases was under 15 per cent., showing that it was not this method of treatment which was the cause of the heavy mortality of twenty-five years ago." The scrupulous cleanliness of the present day, the careful toilet of the peritoneum, the more favourable environment of the patient, and improvements in after treatment are the main causes of the better results, and if the clamp is now inferior to the intra-peritoneal method of treating the pedicle, and has been put aside save in exceptional cases, it was at least an improvement once, and it has but met with a fate which has befallen many another once indispensable accessory, such as the carbolic spray producers, now a drug in the surgical market, but a few years ago playing cheerfully in every surgical ward.

Mr. HUTCHINSON is a strong advocate of specialism in surgical practice, not only in eye diseases, but in stone cases, ovarian cases, laryngeal growths, brain surgery, and surgical diseases of the gall-bladder, and his principles were enforced by his later practice at the hospital of sending his ovarian cases away from the London Hospital to the Samaritan Hospital, a course not always approved by his colleagues, and his present practice of placing all his stone cases

Digitized by Google

under one skilled lithrotrist. In concentration and in nursing homes, with their bright and fair, intelligent and gentle and indefatigable troops of nurses, who never seem to wax even middle aged, he has unbounded confidence. Confidence unbounded he also has in extension of certain operations, such as excision of the tongue for cancer, and henceforth, if the operation be done quite early, no one need die of cancer of the tongue. We trust that it may prove so to be; but can we prevent patients who have lost their tongue in whole or in part from dying of the subsequent glandular affection, however long it may be delayed? If the clamp has given way the doctrine of the local origin of cancer and a precancerous stage will triumph; for "permanent recoveries after removal of the breast for cancer, as after those of part of the tongue for epithelioma, are now common in the practice of all operators." If this assertion is not, as we think, of far too sweeping a character we shall be glad to have it substantiated. In conclusion, Mr. HUTCHINSON referred to surgical education and the five years' curriculum, and he gave another of those autobiographical incidents which give so much charm to his address. Never a warm advocate of the five years' curriculum, and entertaining strong objections to it on the ground of expense and hindrance to many in their career, he has consistently given his vote in committees and the Council chamber in favour of an additional year. Knowing how liberal are Mr. HUTCHINSON'S views, and how strong a reformer he is, we have often wondered how it is that with his great position and opportunities the cause of reform did not make greater progress while he was a member of the Council.

Annotations.

"Ne quid nimis."

PRESENTATION TO SIR JOSEPH LISTER.

ON Tuesday, in the theatre of King's College Hospital, Sir Joseph Lister was presented with a three-quarter length portrait of himself, painted by Mr. Lorimer, A.R.S.A., and an illuminated and illustrated album containing the names of the subscribers. Dr. W. S. Playfair, who presided, said that the testimonial to be presented on that occasion was not to be considered in any way as a recognition of Sir Joseph Lister's great scientific attainments, or even of the proud position which he has achieved for himself as one of the greatest benefactors of humanity who has ever lived. At some distant time, Dr. Playfair averred, those things will be fittingly acknowledged by a national memorial, and he would venture to prophesy that that memorial would not be a national one only, but an international one, for what Sir Joseph Lister had done had conferred benefits upon all the nations of the earth equally. What they did that day was to offer to him from his old friends, colleagues, and pupils a small personal recognition of the affection and esteem which they entertained for him. It was a fitting thing that they had been so fortunate as to secure the coöperation of Sir John Erichsen, who had the privilege of being the teacher of Sir Joseph Lister. The Chairman then called on Sir John Erichsen to make the presentation, who said that in no part of applied science has there been so great progress during the past twenty or thirty years as in that of surgery: so marked and so rapid has been the change that it almost amounts to a revolution. In the art of surgery a new era has come up, old methods have been swept away and distinctly new ones have been introduced, so that it is almost impossible to compare the surgery of the end of the century with that which existed in the later sixties or early seventies. This marked change is due mainly, if not entirely, to the introduction of antiseptic surgery and its appreciation by the profession generally not only in Britain, but throughout the civilised world; indeed, he was ashamed to say that it was more readily accepted and more universally believed in abroad than it was in this country and even in this metropolis. Sir John Erichsen then referred to the brilliant results of the system developed by Sir Joseph Lister, and remarked that he did not think it too much to say that it had raised surgery almost to the rank of an exact science, for the antiseptic method was the result of patient and laborious research begun as early as 1858 in a paper read before the Royal Society on the early stages of inflammation. In 1867 a paper appeared in THE LANCET[1] on the prevention of septic infection in wounds, which was the first of many interesting papers dealing with the gradual evolution of this system. Sir John Erichsen concluded an interesting speech by presenting the testimonial to Sir Joseph Lister, who, in acknowledging the gifts, said that such a gathering of his former colleagues and students brought vividly to his mind the stages of his past professional life. He then sketched his career since he was house surgeon with Erichsen in London and afterwards with Syme in Edinburgh, and described his early experiments in Glasgow, where the antiseptic system had its inception, thanks to the labours of Pasteur, who showed that fermentative changes were caused not by the oxygen of the air, but by micro-organisms. In Edinburgh and London he continued his researches and improved and simplified his methods. In conclusion he feelingly acknowledged his profound gratitude for the memorial. Among the enthusiastic company were Sir George Humphry, Sir George Johnson, Sir Thomas Grainger Stewart, Sir George Stokes, Sir William Priestley, Professor Macewen of Glasgow, Professor Chiene of Edinburgh, Professor William Stirling, Professors Rose and Watson Cheyne of King's College Hospital, Dr. Silk, Dr. Heron, Dr. Wallace, and Dr. Finlayson.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE Council of the Hospital Sunday Fund met on Monday last to receive the report of the Distribution Committee and to sanction the awards. The occasion was interesting for several reasons. In the first place the sum received exceeds that of any previous year. About £44,000 have already been received and £2000 more at least are expected. There is still time for benevolent persons to come to the rescue and make the collection £50,000. Meantime it must be admitted that the clergy of all denominations have put forth noble efforts to make the contribution worthy of the followers of Him who came to "heal the sick" and in every way to minister to the poor. It is a healthy sign that the Distribution Committee does not give blindly and unquestioningly to the various institutions. Rather does it tend to become more careful, not to say critical, in respect of the institutions which it benefits. In the present year no less than 25 institutions were questioned with regard to their administration. Of the 184 institutions enumerated in the appendix of the report, 154 have received awards on a full basis, and 25 on a reduced basis. Five have received none. Nothing serves more to confirm the confidence of the public in the Council of the Hospital Sunday Fund than when it signifies its disapproval of gross faults or defects of administration by reducing or altogether withholding grants. Mr. Burdett gave particulars of a visit to the Queen's Jubilee Hospital, showing it to be an ordinary house, overcrowded with patients and entirely ill-adapted

[1] THE LANCET, March 16th, 1867, et seq.

Digitized by Google

for hospital purposes. The account, with others, amply justified the Council in withholding the award which it had given in some previous years, and out of which an argument in defence of the hospital had been raised. Dr. Glover raised the important question of the Out-patient Department, observing that he considered it the least defensible part of the hospital system, and one which was of doubtful value to the poor, while it brought discredit on the whole administration. He showed that, according to the statistics of the Fund, 1,053,332 patients were treated in this department, but that there was the greatest vagueness as to what these figures meant—whether they were mere visits or actual patients, with no information as to how often the same patient was counted by more than one hospital. The cost of this system, reckoning 3*s.* 4*d.* per head as the average of out-patients, in accordance with the statistics actually before them, was something over £170,000, the saving of which, or part of which, would go far to relieve the finances of the hospitals. Dr. Glover gave notice that he would, at the next meeting of the Council, move for an inquiry into this subject by a subcommittee.

MIRROR WRITING.

IN the *Quarterly Medical Journal* for Yorkshire and the adjoining counties Dr. Crochley Clapham gives an account of a case in which this abnormality was well marked. The patient was a female with right hemiplegia who had taught herself to write with her left hand. At first she wrote wirrorwise—i.e., from right to left; then having gone to school she commenced to write in the usual way, and sometimes forgetting she would write one line mirrorwise and the next in the usual way—the style in which archaic Greek manuscripts were written. Many people practise mirror writing at the present day for the purpose of writing on post-cards, for the writing is illegible, like the books in "Looking-glass House," unless held up to a mirror. It will be found comparatively easy to do if the left hand is used, and still easier if both hands are used simultaneously, and many markedly left-handed persons do it naturally.

THE CONTROL OF INFECTION ON THE FRANCO-BELGIAN FRONTIER

WE learn from the *Moniteur Belge* of July 4th that a very useful system of intercommunication has been arrived at between the French and Belgian Governments as to the notification by each one to the other of the existence of cases of infectious diseases in their respective frontier departments, whether these diseases occur in man or in the lower animals. The French departments concerned are those of the Nord, Aisne, Ardennes, and Meuse, the corresponding Belgian ones being those of West Flanders, Hainaut, Namur, and Luxembourg. The human diseases that have been brought within the terms of this international agreement are Asiatic cholera, typhus fever, typhoid fever, small-pox, scarlet fever, diphtheria, measles, dysentery, contagious ophthalmia, puerperal fever, and "generally all epidemic and communicable diseases." As regards a number of these diseases, it is only intended that information should be forwarded when the occurrence amounts to a definite outbreak or epidemic; and in the case of others, such as dysentery, for example, it is further provided that it is only grave occurrences which are to be notified. But the matter is different with regard to small-pox and cholera, for even a first attack of these two diseases is to be internationally notified. On the part of France this is an entirely new departure; for it was the influence of the French delegates that rendered valueless the system of international notification of cholera proposed at the Dresden Conference, that delegation having induced a majority of the Government delegates to vote in committee with them to the effect that notification was to be limited to the occurrence of a *foyer*, a word that hardly admits of being translated into English, and which no member of the Conference was able satisfactorily to define. The matter has, however, now been somewhat modified as regards a single country, and the terms of the agreement seem to give an indication as to the reasons which made France object to notify anything short of a *foyer* in 1893, for it is explained that any notification given under the new arrangement is not to be followed by the application of the measures of prevention prescribed in the annexe of the Dresden Convention which relates to notification. And, further, the notification is to be deemed on both sides as confidential. We are, however, glad to see even this partial and secret advance in the direction of the unreserved publicity which we maintain in this country. We would not boast of this publicity, for we must confess that it has been invaluable to us in a commercial sense. If foreign countries had suspected us of concealing cholera under the plea that a *foyer* was not fully developed, as has been done elsewhere, we should have been subjected to many restrictions in foreign ports which we are now increasingly able to avoid. The animal diseases which come under a similar reciprocal system between France and Belgium include rinderpest, contagious pleuro-pneumonia, aphthous stomatitis, glanders, farcy, sheep-rot, and scab. As regards these, however, there is no injunction as to secrecy.

FROM PARACELSUS TO PIMLICO.

THE following advertisement appears in a contemporary. We omit names.

"Mr. ——, Pimlico, London, manufactures the very best crystals and the most reliable hollow 'spheres' for mirror vision. The latter are neatly mounted, and both are sent in cases in which they can be carefully kept and protected. As crystal gazing has become so common among those who study the occult sciences, it is well for us to know where we can get the very best balls for our purpose."

It was Thackeray, we think, who remarked upon the wondrous conjunction of the "Hour and the Man"—how when anything is wanted someone is sure to supply it; but that was in romance. There is but little romance in Pimlico. We noticed some of the "very best balls" in the window—some were silvered spheres, such as are hung upon a Christmas tree; some solid spheres, like the common paper-weight; and some globular flasks turned upside down. These last were to be filled with water. Modern occultism is but a poor thing; and how can anyone expect to see visions in a factory-made ball of glass bought out of a shop Compare these with the real magic crystal:—

"The lady unbound her jewelled zone
And drew from her robe the Beryl Stone;
Shaped it was to a shadowy sphere,
World of our world, the sun's compeer,
That bears and buries the toiling year.

"With shuddering light 'twas stirred and strewn,
Like the cloud-nest of the wading moon;
Freaked it was as the bubbles ball,
Rainbow-hued through a misty pall,
Like the middle light of the waterfall.

"Shadows dwelt in its teeming girth
Of the known and unknown things of earth,
The cloud above and the wave around,
The central fire at the sphere's heart bound,
Like doomsday prisoned underground."

With this mirror one might well expect to see anything, but nineteenth-century magic is a weak and feeble following of its ancient ancestors. No doubt we shall soon see quotations for other mystical properties—e.g., "Powder of sympathy, finest selected, per ounce 5*s.* 6*d.* A reduction made to professional prize-fighters and electioneerers. A large selection of rings, keys, Bibles, sieves, birds, cocks always on hand. Arrangements have been made with the authorities of the slaughter-houses at Islington and Deptford for amateur haruspices to practise enteromancy, and strict cleanliness will

Digitized by Google

be observed." The commercial side of modern occultism will give the death-blow to a silly fad, and crystal gazing, fortune telling, and other dabblings with the unseen will pass into the limbo where are stored many another broken toy and plaything of unbalanced intellects.

TELEPHONES AND THUNDERSTORMS.

WE have more than once commented upon the possible danger to persons using the telephone during a thunderstorm. This has been demonstrated most recently at Westoe, in the county of Durham. The *Newcastle Daily Leader* of July 29th states that a gentleman "was using the County Hotel instrument to speak to Newcastle when he received a shock which caused him intense pain and rendered one of his arms powerless." The necessity that every apparatus of the kind be fitted with some arrangement for carrying a strong current to earth without passing through the instrument is, of course, recognised, but are the protecting devices ordinarily used the most efficient for the purpose? We have doubts.

MEDICINE AND THE BRITISH SCHOOL AT ATHENS.

THOUGH the exigencies of scientific and clinical education have reduced to a minimum those medical men who are also Greek scholars, the fact does not imply that the literature, the art, and the history—in a word, the civilisation—of ancient Hellas have in equal proportion lost interest for the profession. On the contrary, we believe that the light thrown by linguistic and archæological discovery on Greek institutions and *chefs-d'œuvre* finds more intelligent and more diffused appreciation among the votaries of medicine nowadays than in previous generations when Greek as a dead language was more frequently a professional accomplishment. It would even seem as if the time saved from grammatical and critical study of the language were now devoted to a more thorough acquisition of the ideas it embodies and the facts it conveys, as if release from the service of commentary and lexicon were appropriately utilised by a closer, kindlier familiarity with the spirit, the genius, to which these scholastic implements were supposed to be the master-key. Grote on the history, Mure on the literature, Otfried Müller on the art of ancient Greece, supplemented by the skilfully arranged treasure-trove of archæology in museums, put the contemporary layman in a better position to understand Hellenic thought and culture than the mere scholar, however "sound," could have worked out for himself a generation previously. The most civilised of modern nations—headed by Germany and France, have long had at Athens, for example, institutions endowed and administered with direct bearing on archæological discovery. America has followed liberally in the same track, and since 1886 Great Britain has also had a similar school. At the great meeting held recently in St. James's Palace, at the invitation and under the presidency of the Prince of Wales, a statement was made as to the condition of that school by no means flattering to the national pride. Of the four Governments, French, German, American, and British, the last is the least liberal in its subsidies of archæological investigation on Hellenic soil, and an earnest appeal had to be made, not only by the Prince of Wales, but by the Duke of Sparta, the Archbishop of Canterbury, Professor Jebb, Sir Frederick Leighton, and Mr. Egerton, our Minister at the Greek Court, for means to bring up the British school to something like equality with its three friendly rivals. In that appeal we fervently join, not only from sympathy with a branch of profoundly interesting research, but from a just sense of what the school referred to has already done, and may still more be expected to do, for the history of medicine. If we dip into any of the later works on this latter subject we shall at once recognise the extent of their obligation to institutions like that now pleading for enhanced resources at Athens. It is safe to say that the interval that divides such histories of the healing art as that of Freind at the beginning of last century and that of Haeser towards the end of this is the interval between the archæology of Queen Anne's and the Victorian reign. Not only in our knowledge of the *armamentarium chirurgicum* of antiquity, but in that of the social life and standing of the practitioners, are we indebted for a clearness and distinctness that the able historians of medicine—the Freinds, the Schultzes, the Sprengels of an earlier day—had no glimmering of. Inscriptions (the science of epigraphy, as it is called) have told us the fees earned by the physician, whether in private life or at the court of imperial Rome—nay, the fortunes amassed, the property bequeathed, by such ἀρχιατροί as Xenophon, who was attached to the body service of the Emperor Claudius. Nor is it only in the knowledge to be gained of the practice and the emoluments, the character and the status, of our illustrious predecessors in the healing art that such institutions as the British School at Athens have laid the profession under obligation. The doctrine, the precept, of the great medical authorities from the Coan school downwards, from Hippocrates to Galen, await much light yet to be thrown upon them by the scholars, British and others, now attached to the institution at Athens. One of the most fertile sources of improved texts of the ancient authors is the papyri to be found in Egypt and the manuscripts lying still unexplored in the Ægean isles as well as the Levant. From these we may one day receive such a revised text of Hippocrates as may throw light on passages that have defied the acumen of Adams and of Littré, of Ermerins and of Fuchs, as we may also obtain such an edition of Galen as will vindicate his mighty name from the apparent contradictions and ineptitudes that disfigure all recensions of his works hitherto known. Services such as these are fully within the scope of the British School at Athens, and if what that school has done for other departments of Hellenic civilisation may be received as earnest of what it yet will do for rational medicine, of which Greece was the motherland, it has fully established a claim on the support of the profession which we should be sorry to think will not one day be liberally met.

DEATH UNDER CHLOROFORM.

THE recent death of a young child under chloroform was the occasion of introducing an important question as to the consent of the parents. The infant son of a labourer suffered from convulsions and difficulty of micturition, and on July 6th, being then twelve days old, it was brought by a nurse to Dr. C. E. Duff, to whom we are indebted for notes of the case. Finding that the prepuce hardly permitted the passage of a probe he recommended circumcision, which was accordingly performed on July 8th at a district nursing home. Chloroform was administered; the child took it well, and was afterwards sent home. On July 15th some hæmorrhage occurred from the suture on the dorsum having cut its way out and allowed the skin of the penis to come forward on the glans and form extensive adhesions. Dr. Duff told the mother to bring the child next day to the district home in order that this might be put right. She accordingly did so, and held the child on her knee during the operation. Chloroform was again administered, and the child took it as well as on the previous occasion. The adhesions were broken down with a probe, the skin was stitched to the corona and the bandaging was finished, when it was observed that the child (who had been coming to nicely) had ceased breathing. The pulse was still beating and the galvanic battery, artificial respiration, &c., were resorted to, but the patient did not

Digitized by Google

revive. The child, though fully under chloroform, was never deeply under it, the total amount given being about two drachms on a towel in a hot room. The father afterwards informed Dr. Duff that another child of his aged eight months had already died in hospital under chloroform administered for the performance of a minor operation. There was no further confirmation of this statement, but if it be true it would seem to show that undue susceptibility to chloroform may, like other idiosyncrasies, run in families. The fact of this previous death was concealed by the parents, who feared that if it were known the operation would not be performed. An inquest was held, very much against the wishes of the parents, but it was exceptionally necessary, as they asserted that the operation had been performed without their consent. This statement, however, was contradicted by the nurse who attended the mother in her confinement, and whose evidence was to the effect that the mother had on five successive days urged her to have something done for the infant's relief. The mother further declared that she heard nothing about the use of chloroform on the first occasion until the child was brought home, and that she did not know that it was administered at the second operation. The coroner, however, pointed out that she must have seen the administration, and Dr. Duff stated that neither was any complaint made by the mother as to the chloroform nor was he informed before the operation that a member of the same family had already died under chloroform. If this had been brought to his knowledge an anæsthetic would not have been given on the present occasion. At the post-mortem examination the body was found to be emaciated, but no organic lesions were discovered. The verdict of the jury was, "Death under chloroform properly administered in the course of a necessary operation."

AUTUMN MANŒUVRES AND SUNSTROKE.

OUR Rome correspondent writes:—"The soldier on the march is peculiarly a 'candidate' for sunstroke, never more so than during those autumn manœuvres now in progress or in preparation throughout Europe. Roused up in the early morning, often after insufficient rest, he has to fall into line and keep pace, in serried column with his comrades, for miles at a stretch, till within an hour or two of noon. His knapsack is no light one; his tightly fitting uniform is doubly tight around the neck; he marches shoulder to shoulder between his brother-privates, getting and giving out body heat, on shadeless, dusty high-roads, under a progressively scorching sun. First his inner clothing gets saturated with perspiration and clings uncomfortably to the skin, an unbearable heat besets his chest, the respiration becomes shallower, and his tongue cleaves to his palate. If the day is one of those warm, steamy ones, familiar as 'a scirocco-day' in Italy, his state is still more distressing, till presently his resisting power gives out; he drags his limbs after him in stolid apathy for a hundred yards or so, and then collapses, in unconsciousness—the victim to sunstroke. The respiratory and cardiac movements are either very weak or scarcely perceptible; sometimes he lies with closed eyelids, snoring stertorously; but the gravest symptom of all is the characteristic irresponsiveness to all external stimuli, especially when accompanied by convulsively compressed lips which make opening of the mouth impossible. Remedial measures can generally save him, even in this condition; but too often they are impotent to avert the fatal issue which mostly supervenes amid violent and general convulsions. Dr. Vollmann's admirable study, 'Ueber den Hitzschlag,' follows up a detailed description of the phenomena summarised above by a minute physiological analysis of their etiology, into which it is beside my present purpose to enter. More opportune is it to signalise the steps he proposes, precautionary and therapeutic, for the prevention and cure of such cases, occurring as they do with monotonous frequency during the Continental autumn manœuvres. Of the former, those which have made most impression in Italy are: (1) the avoidance of unremitting muscular activity in the heat, which, for the soldier, means more frequent halting-places under the shadow, preferably of trees, which themselves are 'refrigerators'; (2) a looser clothing, particularly round the neck, to admit of freer cutaneous transpiration; (3) a less close marching order; and (4) an unfailing supply of cooling beverages. It is at this last point that his Italian critics are less disposed to follow him. Not that they do not share his opinion that 'die weitverbreitete Scheu vor den Gefahren des "kalten Trunkes" ist unbegründet' (the widespread fear of 'cold drink' is unfounded), for the stomachic and intestinal mischief set up by the sudden ingestion of ice-cold liquids is avoidable by their being imbibed gradually or served out in such quantities as will minimise their bulk. But they hesitate to encourage a practice already all too prevalent among Italians, civilian as well as combatant, in the dog days, that of engorging the circulation with liquid from the excessive consumption of 'bibite' and 'bevande' of all kinds so numerous and so easily procurable in Italy. Serous apoplexy, the proximate cause of sunstroke, is directly promoted by this vascular distension — a fact which explains the frequency with which the lesion overtakes the soldier, not on the march, but in quarters and when in bed at night. On the other hand, Dr. Vollmann's warning against alcohol in every form and however freely diluted finds more acceptance among his southern than among his northern readers, while his clear and precise rules for the treatment of the sun-stricken pending the arrival of the medical officer, command universal approval. 'Pending the arrival of the medical officer,' I say, for Dr. Vollmann is completely and admittedly in the right when he insists 'dass nur der sachkundige Arzt im Stande ist im speciellen Fall abzuwägen welche Massregeln gerade geboten sind und wie deren Anwendung zu erfolgen hat' (only the professionally trained physician is qualified to deliberate, in special cases, what measures are directly indicated and how their application is to proceed). His suggestions and prescriptions come with marked opportuneness now that the Italian manœuvres are in progress."

WILHELM MEYER MEMORIAL.

THE following letter, signed by Dr. Semon, as Chairman of the Committee, by the Presidents of the Royal Colleges of Physicians of London and Surgeons of England, and other well-known members of the profession, has been addressed to the general press. We have pleasure in publishing it, as many of our readers will doubtless also desire to take part in the movement.

"With your permission we wish to enlist the interest of your readers in a movement of a somewhat unusual character. Twenty-seven years ago Dr. Hans Wilhelm Meyer of Copenhagen recognised that an enlargement of the glands situated between the nose and the throat, to which he gave the name of 'adenoid vegetation,' was the most fertile cause of deafness and imperfect nasal respiration in children. This discovery represents one of the most important practical advances of modern medicine. Already many thousands of persons through the timely removal of the enlarged glands have been saved from lifelong deafness or from the lasting consequences of obstructed respiration, and it may be safely said that to no one of our contemporaries are we more deeply indebted for the development of a healthy mind in a healthy body of the rising generation than to Hans Wilhelm Meyer. On the recent death of this eminent man it was felt that his unusual merits deserved unusual recognition, and

Digitized by Google

the proposal to erect a statue to him at Copenhagen has met with a most sympathetic reception, not only by his fellow countrymen, but also by the medical profession of other countries. H.R.H. the Princess of Wales has most graciously consented to give her patronage to the scheme, and has expressed her sincere gratification at the idea that so eminent a fellow countryman of Her Royal Highness's should be thus honoured. The municipality of Copenhagen have promised to grant a suitable site for the statue, and at this moment in almost every country committees are being formed for the furtherance of this object. Whilst as a rule the medical profession, when they wish to honour their great living or dead, confine their appeals to the ranks of the profession itself, in the present instance it is thought that an opportunity should be given to the numberless parents of children, whose sound development and the preservation of whose hearing has been rendered possible by Dr. Meyer's discovery, to show their gratitude by contributing towards a memorial in appreciation of his great services. We therefore, through the medium of your columns, venture to invite subscriptions, which may be sent to our honorary treasurer, Mr. A. E. Cumberbatch, F.R.C.S., 80, Portland-place, London, W., and will be duly acknowledged in the journals."

Mr. E. Cresswell Baber, M.B., 97, Western-road, Brighton, and Mr. Ch. A. Ballance, F.R.C.S., 106, Harley-street, W., are the honorary secretaries.

MEDICAL MEMBERS OF PARLIAMENT.

THE General Election, which is now practically concluded, has not resulted in the inclusion of any large number of our professional brethren in the legislative ranks. The following are the names of those practitioners who have been successful in their appeal to the constituencies:—D. Ambrose, M.D.Q.U.I. (Louth, S.); R. Ambrose, L.R.C.P. and S. Edin. (Mayo, W.); G. B. Clark, F.R.C.S. Edin. (Caithness-shire); John Dillon, L.R.C.S.I. (Mayo, E.); R. Farquharson, M.D. Edin., F.R.C.P. Lond. (Aberdeenshire, W.); Sir B. W. Foster, M.D. Erlang., F.R.C.P. Lond. (Derbyshire, Ilkeston); J. F. Fox (whose qualifications we are unable to particularise), (King's County, Tullamore); J. E. Kenny, L.R.C.P. and S. Edin. (Dublin, College-green); M. A. MacDonell, M.D., Q.U.I. (Queen's County, Leix); and C. K. Tanner, M.D., Q.U.I. (Cork, Mid.). All of these gentlemen held seats in the previous Parliament. It may also be noted that Mr. Finlay, the eminent Queen's Counsel, who was elected for Inverness Burgh, was at one time a medical practitioner and is an M.D. Edin. Sir W. Cameron Gull (Barnstable division of Devonshire), also a barrister, is the son of the late Sir William Gull, M.D.

THE ASSOCIATION OF BRUSSELS MEDICAL GRADUATES.

THIS association held its annual meeting on Monday last at the Café Royal. The hon. secretary, Dr. Major Greenwood, and the treasurer, Dr. Younger, were able to report the association to be in a very satisfactory state. The membership exceeds 100 names, and includes many eminent and successful practitioners both in the metropolis and in the provinces. The president for the year is Dr. J. W. Warburton of Liverpool. The existence of the association is a vivid illustration of the fact that in this country there is a grievance to medical practitioners in the unreasonable difficulty of obtaining a degree in medicine at home, and that when they go abroad to receive one on honourable terms it cannot be registered. By Section 16 of the Act of 1886 registered practitioners in possession of such degrees prior to the passing of the Act were allowed to add such as an additional title in the Medical Register. But this does not, of course, help those who have obtained degrees since the passing of the Act. This limitation is difficult to understand or to defend, and is one on the removal of which the association is much bent. Among the guests of the meeting were Sir Walter Foster, Dr. Glover, Mr. Langton, and others.

THE BATTLE OF THE CLUBS AT BRUSSELS.

THE Brussels medical practitioners have been able to present a practically similar solid front to the clubs to that shown by their brethren in Cork and other British towns where attempts have been made to prevent well-to-do persons from obtaining professional services on ridiculously inadequate terms. Though more than 400 practitioners in the Belgian capital agreed not to accept the club appointments under existing conditions, six qualified men have at last been found willing to brave the public opinion of the profession for the sake of these miserable appointments. Whether the clubs will be happy now that they have secured six out of the twenty surgeons they require remains to be seen. In order to excuse themselves somewhat these gentlemen have not thought it beneath their dignity to write to the daily papers explaining that their acceptance of the appointments is merely due to "motives of humanity."

MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS.

THE School Board may well say with the character in the Greek play, "Woe adds woe to woe." At the meeting held on July 23rd Mr. Athelstan Riley asked Mr. Sharpe, the chairman of the School Accommodation and Attendance Committee, "Whether, since the letters received (1) from Captain Blount, R.N., secretary of the Victoria Hospital for Children (stating that, until the resolution passed by the Board on May 30th, 1895, is rescinded, the staff will decline to give certificates to children attending the hospital though they may think it desirable that the child should be excused from attending school), and (2) from the secretary of the Paddington Green Children's Hospital, dated July 10th, 1895, in the same sense, the following letter has been received from the secretary of the North West London Hospital:—

"17th July, 1895.

"GENTLEMEN,—I beg leave to inform you that the medical and surgical staff of this hospital have decided that, should the resolution passed by your board on May 30th, 1895, a copy of which I enclose, be carried into effect, they will in future decline to give any certificate of unfitness to attend school for children under treatment here."

To which Mr. Sharpe again replied, "Yes." We warned the Board as long ago as June 8th what would be the result of their impertinent interference between medical men and their patients, and until the resolution of May 30th be rescinded the Board may expect other hospitals to follow the lead of the three which have already written. The School Board seem to think that because they have the ratepayers' pockets to pick they can set up an "imperium in imperio" and do exactly what they please without being called to account. It is not long ago that a proposal was made that the Board should have their own special magistrates, who, we imagine, could be trusted never to give a decision adverse to that august body. The ordinary London magistrate, we suppose, was not to be trusted any more than the ordinary London medical man. However, in this matter of certificates the Board have gone too far, and they will have to climb down.

WE deeply regret to announce the death of Sir John Tomes, F.R.S., F.R.C.S., and L.D.S., which occurred on July 29th at Caterham. He was perhaps the first of scientific dental surgeons, and his papers on Dental Anatomy are most valuable contributions to a better understanding of the diseases affecting the teeth. We shall publish an extended obituary notice next week.

UNDER date Zurich, July 29th, "A Holiday Contributor" writes: "The Zurich Cremation Society has just held its

Digitized by Google

annual meeting, and, according to the secretary's report, its members amount to 1087, and the funds at its disposal to 10,200 fr. In the course of 1894 the corpses cremated were in number forty. The price for each cremation is now fixed at 65 fr. for persons deceased in Zurich—being a reduction of 30 fr. on the price charged for the non-resident deceased, that is, for the migratory or tourist population.

THE annual Congress of the British Institute of Public Health will be held at Hull from the 8th to the 13th inst. The hon. president of the Congress is the Most Hon. the Marquis of Ripon, K.G. The president is Mr. Alderman Richardson, Mayor of Hull, and the president of the institute is Professor W. R. Smith. The subjects of papers and discussion include every matter of importance in the way of public health, and in addition an inviting social programme has been arranged.

DR. FRANCIS WARNER has been appointed a honorary member of the Society of Hygiene at Budapest.

METROPOLITAN HOSPITAL SUNDAY FUND.

A COUNCIL MEETING of this Fund was held on Monday, July 29th, at the London Mansion House, to receive the report of the Committee of Distribution for the year 1895 and to approve of the several awards recommended by that committee. Sir Sydney Waterlow occupied the chair, and among those present were Cardinal Vaughan, Archdeacon Sinclair, Sir Savile Crossley, Canon Fleming, Canon M'Cormick, Mr. Henry C. Burdett, the Rev. J. F. Kitto, Captain Cundy, Dr. Glover, Mr. Wakley, Rev. W. H. Barlow, Mr. W. R. Tidd, Mr. F. C. Carr-Gomm, Mr. Alfred Willett, the Rev. A. A. Harland, and others.

In moving the adoption of the report the CHAIRMAN said the work of the committee had been very heavy this year as the accounts of a large number of hospitals had been questioned. Some of the complaints had been cleared up to the committee's satisfaction, some only partially, and in a large number of cases they had been obliged to put the word *nil* against the application. Awards had been recommended to 179 institutions, being an increase of 74 since 1873. This accounted to some extent for the increased work of the committee, but he thought it only just to his colleagues to say how very thoroughly the accounts had been investigated. The total amount for distribution was £44,410, but he hoped that before the accounts were closed the sum would reach the amount the Council were asking for—namely, £50,000. There certainly was never a time when the Fund more needed support because the number of empty beds to be utilised if funds were forthcoming would be of the greatest benefit to the sick poor. As usual 5 per cent. of the total collected would be set apart for the purchase of surgical appliances. This year they had had occasion to question the administration of no less than twenty-five institutions, each of which had been given the opportunity of sending a deputation in conference. Twelve deputations were interviewed, and in the other cases the matter was settled by correspondence. Three institutions not having published their accounts on the uniform system agreed upon were ineligible. One convalescent home, where the charge for maintenance of patients was deemed excessive, has only a small award recommended; and in one case where a dispensary, having its accounts largely involved in mission work, was recommended only so far as the medical work of the mission was concerned, and upon the understanding that in future the financial statements should show the dispensary and the mission work separate. This was not because the committee desired to find fault with mission work, but it was felt that the Fund was not raised for that purpose. He hoped and believed that the discussions with the managers this year would lead to a considerable improvement in the administration of these institutions.

Archdeacon SINCLAIR, who seconded the motion, said he was glad to see signs of growth in the Fund. At St. Paul's a great effort had been made and he was happy to say the donations had been almost doubled. This was due to previous careful work among the congregation and nobody knew this better than Canon Fleming. If all ministers would prepare the ground beforehand and not trust to their sermons alone on Hospital Sunday, much larger collections would result. He thanked THE LANCET and the *Hospital* for the interesting, vivid and effective manner in which the facts were put before ministers. It needed only a very little re-arrangement on the part of the clergy to enable them to prepare their sermons.

Mr. BURDETT, in supporting the motion, congratulated the committee upon the work they had done. He referred to the practice adopted by the Dublin Hospital Sunday Fund, which gave no grants until the institutions concerned had first been inspected by representatives of the Fund. Acting upon this he thought it might be useful if he paid a visit to the Queen's Jubilee Hospital, which had been refused a grant by this Fund, and he was bound to tell the Council that it was not a hospital at all. It was an overcrowded tenement house where sick people are wrongly taken in for medical treatment. So overcrowded was it that it was a marvel to him that it was allowed to exist, seeing that there was a local medical officer and also a very able medical officer for London.

Dr. GLOVER heartily concurred in all that had been said, and rejoiced in the increased sum which had accrued to the Fund. Referring to the statistics prepared by the Council, he drew attention to the enormous sums spent by hospitals upon their out-patients. He gave notice that at the next meeting of the Council he would move for the appointment of a subcommittee to investigate the statistics of the out-patient departments. He contended that if the number of these patients could be greatly reduced there would be a great saving of expenditure which would considerably relieve the hospitals, and greatly add to the public confidence in hospital administration.

Sir SYDNEY WATERLOW quite agreed with the appointment of a subcommittee for this purpose, but pointed out that the Committee of Distribution already had a return showing how many new patients there were attending in each case, and the statistics were based on the number of new patients rather than on the number of attendances.

The motion was unanimously carried.

Canon FLEMING moved "That the cordial thanks of the Council be and are hereby given to Sir Sydney H. Waterlow, Bart. (chairman), and to the other members of the Committee of Distribution for the considerable care and attention bestowed in the preparation of the awards they have recommended, and for the very efficient report of their proceedings." Sir Sydney Waterlow had been connected with the committee for nearly a quarter of a century, and they could not help feeling that he was really the father of the Fund.

Mr. CARR-GOMM seconded the motion, which was heartily carried.

In thanking the Council the CHAIRMAN remarked that they had just received notice of a legacy of £200 from Miss Mary Evans.

Mr. BURDETT, proposed: "That the thanks of the Council be and are hereby given to the editors of newspapers who have pleaded the needs of hospitals and advocated the cause of this Fund, with a view to increasing this years' collection." It has been our custom, he said, to propose this resolution at this meeting every year, but never had it been so well deserved as in the present year, for the editors of the entire press had united to endeavour to raise the Fund to at least £50,000. He pointed out the concession made by Mr. Walter of the *Times*, who, in the cause of charity, admitted for the first time in its history diagrams into the advertisement columns facing the leaders. Although the Fund up to the present had not reached £50,000, the accounts did not close until October, and a very little effort should bring in the required balance. What was wanted was a wider distribution of givers and a larger number of individual gifts. The resolution was a general one, and of course some editors, from the character of their newspapers, had done more than others; still, it was felt that the whole press had helped the Fund, and it was only by their united efforts that the greatest good could be done. But those who were on the Council of the Hospital Sunday Fund could never forget that the first step in the upward growth of the Fund came from the Editor of THE LANCET. It was the late Dr.

Digitized by Google

Wakley who first stirred up the Council to a special effort and brought them out of the twenties into the forties, and now they were near into the fifties. His brother every year spent a large sum of money, a great deal of time, and gave to the Fund much personal interest; the latter he thought of more importance than money. Mr. Wakley was untiring—and he (Mr. Burdett) thought it only just that he should say so—in trying to get new ideas for the benefit of the Fund.

Cardinal VAUGHAN, who seconded the resolution, said that no one who took interest in the work, and whose duty it was to put the claims of the Fund before their congregations, could be otherwise than deeply indebted to THE LANCET for the attractive way in which the whole question was brought before its readers. THE LANCET rendered an important public service to a great charity in which the whole city was interested, and it was only right and just that its labour should be recognised in an ample and thorough manner. While he thanked the whole of the press, he thought a special meed of praise should be given to those medical papers which had done so much to promote the interests of the Fund.

Sir SYDNEY WATERLOW said he could not put this resolution before thanking all editors, but especially Mr. Wakley who had spared every year, and particularly this year, neither time, trouble, nor expense in doing everything which he thought would benefit the Fund. He desired also to personally thank Mr. Burdett for the special way in which he had caused the movement to be known in the West-end. The resolution was then carried *nemine contradicente*.

The Rev. J. F. KITTO proposed "That the cordial thanks of the Council are now given to the Right Honourable Sir Joseph Renals, Bart., Lord Mayor, who, as President and Treasurer, has devoted his valuable time to promote the growth of the Fund." This motion being carried, the usual courtesies to the chairman terminated the proceedings.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on July 29th, the President, Mr. CHRISTOPHER HEATH, being in the chair.

The Secretary laid before the Council the certificate of the auditors, Messrs. Cooper Bros. and Co., certifying to the accuracy of the accounts of the College for the past year 1894-95, and a balance-sheet dated June 24th, 1895. The statement of receipts and expenditure and the balance-sheet were approved and adopted, and were ordered to be published in the College Calendar.

A report, dated July 15th, from the Committee of Management was approved and adopted. It was as follows:—

1. That the following institution be added to the list of places of instruction in chemistry, physics, and practical chemistry—viz., the Grammar School, Bedford. 2. That the following institution, already recognised as a place of study in chemistry, physics, and practical chemistry be also recognised for biology—viz., Dulwich College. 3. That on the application of the Dean of St. Mary's Hospital Medical School, the course of clinical demonstrations in lunacy given by Dr. T. B. Hyslop at Bethlem Hospital be recognised so long as he shall hold the lectureship in psychological medicine at St. Mary's Hospital Medical School. 4. That on the application of the Dean of University College, Bristol, the Fever Hospitals of the Bristol Public Health Department be recognised as fulfilling the requirements of the regulations for attendance on fever cases. 5. That the Great Northern Central Hospital be recognised as a place of study during the fifth year of the curriculum.

A second report, dated July 25th, was read from the committee on the proposed arrangements for the Third and Fourth Examinations. The report was approved and adopted. It was as follows:—

In pursuance of the resolution adopted by the Council on June 13th, 1895, the committee have again taken into consideration the following recommendations contained in their report of June 7th, 1895—viz.: 1. That a separate examination in ophthalmic surgery be not instituted. 2. That Paragraph 11, Subsection II. of Section I. of the Regulations for the Five Years Curriculum be altered by the addition of the words herein printed in italics—viz: 11. Of having attended clinical instruction in ophthalmic surgery *and discharged the duties of dresser* at an ophthalmic hospital recognised for the purpose by the Examining Board in England, or in the special ophthalmic department of a recognised general hospital during not less than three months (candidates may fulfil this requirement any time after passing the second examination).

The committee have also, in pursuance of the instructions of the Council, consulted the medical schools upon the question of examination in and teaching of ophthalmic surgery. The committee, having again considered the matters referred to them, do not think it desirable that any addition should at the present time be made to the regulations respecting the examination and teaching of ophthalmic surgery. The committee therefore again recommend to the Council that a separate examination in ophthalmic surgery be not instituted, and do now recommend that no alteration should be made in Paragraph 11, Subsection II. of Section I. of the Regulations for the Five Years Curriculum but that it should remain as printed above without the addition of the words in italics.

The committee, in pursuance of the permission accorded to them by the Council, have obtained a report from the Court of Examiners on the details of the arrangements proposed by the Committee of Management for the Third and Fourth Examinations. The committee, however, are unable to report upon these details, as they think it desirable that the whole question of the examinations under the five years curriculum should be reconsidered. The committee therefore recommend to the Council that they should be authorised to consider and report upon the general scheme of examinations, as well as upon the details, and that they should further be authorised to consult the medical schools, if they should think it desirable.

It was moved and adopted that the Royal College of Physicians of London be informed that the Council had not adopted the recommendation of the Committee of Management contained in their report of March 18th, 1895, respecting the institution of a separate examination in ophthalmic medicine and surgery; and a copy of the report presented at this meeting was directed to be sent to the Royal College of Physicians.

The President stated that the Deputation Committee had received a deputation of Members on July 26th, and would submit a report thereon to the Council at a future meeting.

It was resolved that the annual meeting of Fellows and Members should be held at the College on Thursday, Nov. 7th next, at 3 o'clock P.M.

A letter was read, dated July 22nd, from Mr. H. Percy Dunn, reporting the following resolution, adopted by the Committee of the Association of Fellows—viz.:—"That the attention of the President and Council of the Royal College of Surgeons, England, be drawn to the fact that the half-yearly meeting of the Fellows on the 4th instant was closed without any discussion being possible in respect to the business on the agenda, and that, in the opinion of the Committee of the Association of Fellows, such a mode of conducting these meetings would be destructive of the privileges conceded by the Council to the Fellows, and would render their meetings nugatory."

It was resolved that Mr. Percy Dunn should be informed in reply "That the Council wished to point out that the meeting of Fellows was held and conducted in strict accordance with the regulations appertaining to the meeting; that as there were no notices of motion on the agenda paper no discussion could properly take place, the regulations of the meeting requiring previous notice of twenty-one days."

The Secretary reported the presentation to the College by Mr. Jabez Hogg, M.R.C.S., of sixteen daguerreotypes of physicians, surgeons, and others, mostly taken by himself in "the early forties"; nine volumes of scientific pamphlets, and a portrait in oil of a surgeon (name unknown), date 1677. The best thanks of the Council were accorded to Mr. Jabez Hogg for his present.

A letter, dated July 26th, was read from Dr. Liveing reporting the proceedings of the Royal College of Physicians of London in relation to matters common to the two Colleges, and stating that the petition from the London School of Medicine for Women had not been referred to a committee for report, but that its consideration had been postponed to a special meeting of the College to be held towards the close of October or in the early part of November next.

It was moved and carried that the resolution of the Council at the last meeting, referring the petition of the London School of Medicine for Women to the Committee of Management, be rescinded. It was resolved that the further consideration of the petition of the London School of Medicine for Women be postponed to the ordinary meeting of the Council in November.

Mr. Smith moved, "That the question of the admission of women to the examinations for the Diploma of Member be submitted to the meeting of Fellows and Members on the 7th November." The motion was carried.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6356 births and 4572 deaths were registered during the week ending July 27th. The annual rate of mortality in these towns,

Digitized by Google

which had risen in the six preceding weeks from 15·4 to 21·9 per 1000, further increased last week to 22·5. In London the rate was equal to 23·0 per 1000, while it averaged 22·1 in the thirty-two provincial towns. The lowest rates in these towns were 11·8 in Brighton, 13·6 in Huddersfield, 13·7 in Bristol, 14·5 in Croydon, and 15·2 in Gateshead; the highest rates were 28·6 in Birkenhead, 29·5 in Salford, 30·0 in Liverpool, 30·1 in West Ham, and 31·5 in Preston. The 4572 deaths included 1255 which were referred to the principal zymotic diseases, against 877 and 1137 in the two preceding weeks; of these, 903 resulted from diarrhœa, 156 from measles, 77 from diphtheria, 53 from whooping-cough, 39 from scarlet fever, 22 from "fever" (principally enteric), and 3 from small-pox. No fatal case of any of these diseases occurred last week in Halifax; in the other towns they caused the lowest death-rates in Brighton, Bristol, Huddersfield, and Newcastle-upon-Tyne, and the highest rates in West Ham, Leicester, Liverpool, Preston, and Sheffield. The greatest mortality from measles occurred in Plymouth, West Ham, Blackburn, Manchester, and Liverpool; from scarlet fever in Salford; from whooping-cough in Cardiff; from "fever" in Burnley; and from diarrhœa in Bradford, Norwich, Leicester, Sheffield, and Preston. The 77 deaths from diphtheria included 48 in London, 4 in West Ham, and 4 in Wolverhampton. Two fatal cases of small-pox were registered in Oldham and 1 in London, but not one in any other of the thirty-three large towns. There were 193 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, July 27th, against numbers increasing from 19 to 89 at the end of the six preceding weeks; 114 new cases were admitted during the week, against 17, 36, and 23 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2347, against 2044, 2241, and 2267 on the three preceding Saturdays; 249 new cases were admitted during the week, against 311, 342, and 220 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 187 and 193 in the two preceding weeks, declined again last week to 185, but were 8 above the corrected average. The causes of 50, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Newcastle-upon-Tyne, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3 and 18·2 per 1000 in the two preceding weeks, was 18·3 during the week ending July 27th, and was 4·2 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·3 in Perth and 15·2 in Aberdeen, to 23·2 in Paisley and 25·1 in Greenock. The 527 deaths in these towns included 64 which were referred to diarrhœa, 11 to measles, 7 to whooping-cough, 4 to diphtheria, 3 to scarlet fever, 3 to "fever," and not one to small-pox. In all, 92 deaths resulted from these principal zymotic diseases, against 121 and 91 in the two preceding weeks. These 91 deaths were equal to an annual rate of 3·2 per 1000, which was 3·0 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 72 and 61 in the two preceding weeks, rose again to 64 last week, of which 34 occurred in Glasgow, 8 in Greenock, 6 in Dundee, and 6 in Paisley. The deaths referred to measles, which had declined from 18 to 8 in the three preceding weeks, increased to 11 last week, and included 3 in Glasgow and 3 in Edinburgh. The 7 fatal cases of whooping-cough showed a further decline from the numbers recorded in recent weeks, and included 4 in Glasgow. Of the 4 deaths from diphtheria 2 occurred in Edinburgh, 1 in Leith, and 1 in Glasgow. The fatal cases of scarlet-fever, which had been 6 in each of the two preceding weeks, declined to 3 last week, of which 2 occurred in Glasgow and 1 in Leith. The deaths referred to diseases of the respiratory organs in these towns, which had been 80 and 57 in the two preceding weeks, were 59 last week, and exceeded by 10 the number in the corresponding period of last year. The cause of 45, or more than 8 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·0 and 25·1 per 1000 in the two preceding weeks, declined again to 23·9 during the week ending July 27th. During the past four weeks of the current quarter the death-rate in the city has averaged 23·5 per 1000, the rate during the same period being 21·4 in London and 16·4 in Edinburgh. The 160 deaths registered in Dublin during the week under notice showed a decline of 8 from the number in the preceding week, and included 28 which were referred to the principal zymotic diseases, against numbers increasing from 9 to 21 in the four preceding weeks; of these, 24 resulted from diarrhœa, 3 from whooping-cough, 1 from "fever," and not one either from small-pox, measles, scarlet fever, or diphtheria. These 28 deaths were equal to an annual rate of 4·2 per 1000, the zymotic death-rate during the same period being 6·9 in London and 2·3 in Edinburgh. The fatal cases of diarrhœa, which had steadily increased from 3 to 16 in the five preceding weeks, further rose to 24 last week. The 3 deaths referred to whooping-cough corresponded with the number in the preceding week. The 160 deaths in Dublin last week included 51 of infants under one year of age, and 33 of persons aged upwards of sixty years; the deaths of infants showed a further increase upon those recorded in recent weeks, while those of elderly persons showed a slight decline. Seven inquest cases and 7 deaths from violence were registered; and 43, or more than a fourth, of the deaths occurred in public institutions. The causes of 12, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

INDIA AND THE INDIAN MEDICAL SERVICES.

SURGEON-MAJOR C. MONKS is appointed to act as Civil Surgeon, Karachi, during the absence of Brigade-Surgeon-Lieutenant-Colonel G. Bainbridge, M.D., on privilege leave. Surgeon-Lieutenant-Colonel S. B. Haliday, in medical charge, 13th Bombay Infantry, at Aden, having been recommended for twelve months' leave to England on medical certificate, has proceeded home in the *Dilwara*.

ARMY MEDICAL SCHOOL AT NETLEY.

The prizes to the successful candidates at the recent examinations for the British and Indian Medical Services were distributed at the Army Medical School, Netley, on Wednesday last. Sir Joseph Fayrer, K.C.S.I., presided.

It has been decided that medical officers, whether they belong to the military medical service or are civil practitioners, who have served eighteen years on the staff of volunteer corps and have rendered substantial service to their corps, may be considered eligible for the Volunteer Officers Decoration.

The following rules, says the *Pioneer Mail*, have been laid down for the grant of pay to a Brigade-Surgeon-Lieutenant-Colonel of the Indian Medical Service during the period he is attached to the office of a Principal Medical Officer for the purpose of acquiring a knowledge of military medical administration:—(1) In cases where it is practicable to attach the officer to the office of a Principal Medical Officer without his relinquishing his civil duties, his full civil pay will be continued to him; (2) in cases where the officer has been obliged to relinquish his civil duties he will be allowed the grade pay of his rank, together with half the difference between that grade pay and the substantive pay of his civil appointment, the whole to be a charge against the military estimates.

THE RETIREMENT OF THE DUKE OF CAMBRIDGE.

It is understood that H.R.H. the Duke of Cambridge, who has left London for Homburg, will on his return vacate his present appointment as military head of the army. There has naturally been a good deal of interest and speculation excited as to the Duke's successor. It seems to be generally agreed that in point of military rank, service, and reputation Lord Wolseley has the strongest claims for the appointment. The Duke of Connaught is undoubtedly very popular and has the reputation of being an excellent officer, in addition to the fact that the present Government would probably desire to see a Royal Commander-in-chief,

Digitized by Google

and it is therefore confidently predicted in some quarters that he is to be the next occupant of that post. But it cannot be contended that in experience, tried ability, and services in the field he has the reputation of Lord Wolseley, Lord Roberts, or Sir Redvers Buller, nor, as it seems to us, would it be in the Duke of Connaught's interest, considering his present age, to be promoted to a post which he would only occupy for a fixed period before retirement. It may, we think, be regarded as certain that nothing has as yet been definitely decided on. The question is one of national and military interest and does not specially concern the medical profession, but the appointment of a Commander-in-chief is likely to affect in many ways the Army Medical Staff in common with other branches of the service.

THE FRENCH IN MADAGASCAR.

It appears that the French troops, especially those in connexion with the river service, have suffered much from dysentery and rheumatic ailments, in addition to climatic fever. There are a large number of young soldiers in the French force, and these are said to have been affected disproportionately as compared with the older and more matured troops. A number of sick soldiers have been sent to the hospital establishments at Réunion. It is understood that those invalided to France were, speaking generally, much improved in health on their arrival at Marseilles; but several soldiers died on the voyage. Some complaints have been made of the arrangements for the disembarkation of troops and stores on their arrival in Madagascar from France, and a good deal of difficulty has been experienced in regard to the commissariat and food supplies for the force. The French hospital service has had its hands full of work. It must be remembered that expeditions of this nature are necessarily attended with great difficulties, and that a good deal of sickness may be confidently expected to ensue, more especially at the beginning of the campaign; at least that has been the experience of this country. The Ashanti expedition was probably one of the best-thought-out and arranged expeditions that England has undertaken.

THE CHITRAL FORCE.

Nothing has yet been definitely settled as to the policy to be pursued in regard to the late Chitral expedition—whether we are to retain our present position in that country or not. It is understood that the more prominent military authorities in England are on the whole decidedly opposed to our remaining, and there are grave political reasons against our doing so, except for very strong strategical considerations, on account of the increased expenditure and the depressed state of Indian finances at the present time. Be this as it may, however, the climate of some of the hill stations held by the Relief Force is said to be excellent during the summer months, and, notwithstanding the sickness that prevails at some stations, the health of the force as a whole is good. The *Pioneer Mail* of July 10th states that the percentage of sick, including those in the base hospitals in the Punjab, is under 7 per cent.

FILTERS FOR BRITISH TROOPS IN INDIA.

We are very glad to learn that a reference has been made to the principal medical officer of Her Majesty's Forces in India as to the desirability of adopting the Pasteur filter for British troops. This should, in our opinion, certainly be done, especially in stations where enteric fever has prevailed. The filter in ordinary use in barrack rooms in India is rather a source of danger than a safeguard against water-borne disease. We have, as our readers are aware, for a long time advocated the introduction of another form of filter for barrack and hospital use in India, and the experience obtained of late years in the French Army shows conclusively what can be done in this direction in improving the health of the troops.

SURGEON-COLONEL CUFFE, C.B.

The death of this officer, which was announced in some of the English and Irish papers, is, we are glad to say, incorrect. Surgeon-Colonel Cuffe, who is Principal Medical Officer of the Allahabad District, according to an Anglo-Indian contemporary of the 10th ult., was at Pachmarhi and in excellent health.

The Leeds Company of the Volunteer Medical Staff Corps will arrive at Netley to-day, Saturday, August 3rd, for their annual training at the Royal Victoria Hospital.

Eleven invalids arrived at Netley from Mauritius on July 31st.

Correspondence.

"Audi alteram partem."

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE PORTRAIT OF SIR JOSEPH LISTER.

To the Editors of THE LANCET.

SIRS,—I am sorry that Mr. C. B. Keetley, in a letter to THE LANCET of July 27th, objects to the plan we have adopted for obtaining a good portrait of Sir Joseph Lister, to be presented to the Royal College of Surgeons of England. A mandate from so large a body as the Fellows and Members of the College, to whom we have appealed, could only have been obtained after considerable delay, expense, and publicity. It seemed, therefore, best to form a committee in which each of the metropolitan medical schools should be represented, and from this committee we purposely excluded members of the Council, as they would be ultimately the recipients and custodians of the portrait. We should also have asked representatives from the provincial schools of medicine had we not thought that such a step would have caused delay. The choice of an artist was made by the committee after consulting the wishes of Sir Joseph Lister. I may also add that our project has the approval and support of the President and most of the members of the Council of the Royal College of Surgeons. I deeply regret that from various reasons we failed to place upon our first list of subscribers the names of many eminent surgeons, who have since welcomed and supported our project with the utmost cordiality; and I trust that any imperfections which may be found in the inception of the work will not prevent the Members and Fellows of our College from doing their best to show by this memorial their appreciation of the unrivalled claims of Sir Joseph Lister to the gratitude of British surgeons.—I am, Sirs, yours obediently,

N. DAVIES-COLLEY,
Treasurer of the Lister (College of Surgeons) Portrait Fund.

July 31st, 1895.

To the Editors of THE LANCET.

SIRS,—Although an ardent and enthusiastic admirer of Sir Joseph Lister, might I be permitted to express the opinion that the time has not yet arrived when anything like a general appeal should be made to commemorate the enormous benefits which his genius has conferred upon mankind in general and the surgical art in particular. If the College wish to add to their collection of portraits they should surely do so out of their corporate funds, or the individual members of the Council should provide the necessary money. An additional objection to the appeal which has just been issued is, that it follows so closely upon the footsteps of one made to Sir Joseph Lister's former colleagues and pupils that practically the latter cannot be expected to subscribe, so that the resulting list of contributors will not by any manner of means represent the full measure of the veneration and esteem with which Sir Joseph Lister is regarded by the profession at large.

I am, Sirs, yours obediently,
"LISTERITE."

London, July 27th, 1895.

"THE CARDIO-VASCULAR CHANGES OF RENAL DISEASE."

To the Editors of THE LANCET.

SIRS,—Sir George Johnson's letter in your last issue chiefly traverses old ground, upon which I need not follow him, as I have so recently ventured upon it. The main purpose of my lecture was to put forward the observations on the large arteries which I had supposed to possess more of novelty than Sir George Johnson allows to them. They may be worth little or nothing, but even a small fact may be of use. I am far from supposing that we have got to the end of a difficult and complicated question, the complete solution of which must be the work of the future. In the meanwhile we want more facts, especially with reference to the state of the capillaries as seen with the microscope. It will be my endeavour to do something in this direction, should I not be fortunately anticipated by some younger and more active observer.

Digitized by Google

Before laying down my pen let me congratulate Sir George Johnson on his recognition in process of time of the fibrous thickening as well as the muscular. He may say with an earlier philosopher, "Whatever I said last Wednesday I do not say so now." This is wholly to his credit, but let it also be placed to the credit of the departed pathologists to whom we owe our knowledge of the arterial fibrosis, which, though not the whole matter, is a part of it which is now no longer a matter of dispute.—I am, Sirs, yours truly,

W. HOWSHIP DICKINSON.

"THE ASSOCIATION OF WORKERS IN ASYLUMS FOR THE INSANE."

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of July 27th, under the above heading, that a meeting has been held at which Sir B. W. Richardson delivered an address. He is reported to have said that "education and training raised the status and increased the usefulness of nurses, and this experience will no doubt be repeated when the same conditions are applied to attendants on the insane." I cannot allow such a statement as this to pass unchallenged. For many years past the attendants and nurses on the insane have been carefully educated and trained. After a period of two years, during which the attendants and nurses have to attend a dozen lectures and the same number of clinical demonstrations in the wards of a hospital for the insane, they are examined, and, if successful, are granted a certificate of proficiency in nursing the insane. The superintendent of the hospital trains his attendants and nurses, but he has nothing to do with their examination. The written portion is conducted by examiners appointed by the Medico-Psychological Association of Great Britain and Ireland, and the clinical and *viva voce* part by an examiner who is generally the superintendent of a neighbouring asylum. The severity of the examination is shown by the fact that at every examination a number of candidates are plucked. The result of the education, training, and examination has been to increase the usefulness of the nurses and attendants, who now take a more intelligent interest in the cases under their care; while, as regards their status, it is quite on a par with hospital trained nurses. Indeed, some of the latter are anxious to obtain the certificate, and a scheme is on foot for admitting them to the examination after a definite period of training. Altogether more than 1000 nurses and attendants possess the certificate which is granted by the Medico-Psychological Association of Great Britain and Ireland.

I am, Sirs, yours faithfully,

FLETCHER BEACH,
Honorary General Secretary, Medico-Psychological Association of Great Britain and Ireland.

Welbeck-street, W., July 30th, 1895.

THE HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN-SQUARE.

To the Editors of THE LANCET.

SIRS,—We shall be obliged if you will kindly allow us to state in your columns that we have now entirely severed our connexion with the Throat Hospital in Golden-square.

We are, Sirs, yours faithfully,

SUTHERLAND,
Lately President of the Throat Hospital, Golden-square, London.

R. COURTENAY WELCH,
Lately a member, and for nearly twelve years chairman of the Committee of Management of the Throat Hospital.

GREVILLE MACDONALD,
Lately Dean of the Medical School, and for eight years physician to the Throat Hospital.

Stafford House, St. James's, July 31st, 1895.

THE PHYSIOLOGY OF DEATH BY ELECTRIC SHOCK.

To the Editors of THE LANCET.

SIRS,—An annotation in THE LANCET of July 27th attributes death in electric shock to "stoppage of the heart." It is useful to inquire how and why this stoppage occurs. Dr. A. M. Bleile (Ohio) has lately investigated the physiological events which in his opinion lead up to it.[1] Experimenting upon dogs with strong currents of stated strength he finds, on examining the heart immediately after death, that "the left side is completely relaxed and the right side intensely gorged with blood, as are also the large veins in the immediate vicinity of the heart. ..... Incisions into the animal are not followed by bleeding, and the arteries are contracted down to a very small calibre." It was suggested, therefore, "that the current acted upon the arteries through the nervous centre which controls their diameter." To test this view dilatation of the arteries and fall of blood-pressure was effected by bringing the animal under the influence of nitrite of amyl. Under these circumstances a current of 0·24 ampères at 52 volts for three seconds (ordinarily a fatal dose) did not produce death. The conclusion arrived at is "that death in electric shock is really due to the fact that the current produces a contraction of the arteries through an influence on the nervous system, and that this constriction of the arteries throws in such a mechanical impediment to the flow of the blood as the heart is unable to overcome, and that where drugs are given to counteract this effect much larger doses of electricity than the ordinary can be borne." The experimental data on which this opinion is based are given in such detail that the experiments can be repeated and results verified. The paper is a useful contribution to the physiology of death by electric shock. It may be incidentally mentioned, however, that the absolute amount of mechanical energy used, as measured in "joules," does not necessarily bear any direct relationship to the physiological effects of an electric current. In other words, a weak current for a long time is a very different thing from a strong current for a short time, although in each instance the "joules" may be the same.

I am, Sirs, yours faithfully,

Brighton, July 30th 1895. W. S. HEDLEY.

THERAPEUTICS OF THE GOLD SALTS.

To the Editors of THE LANCET.

SIRS,—Some few weeks ago, after applying to various wholesale chemists without any result, I enquired through your columns if solutions of the tribromide of gold combined with oxybromides of arsenic, &c., were manufactured, or could be manufactured, in England, being anxious to give them a therapeutical trial. I am glad to say that these preparations now have, at my suggestion, been placed on the English market by Messrs. Arthur and Co. of Berners-street, who have taken considerable trouble over the manufacture of these not easily made solutions. I believe, with an eminent American authority, that these solutions present the tri- and the oxy-bromides in the best possible form of administration, and they have in my hands already proved serviceable in cases of neurasthenia, nervous fibrillary twitchings, &c. I hope English practitioners will give these solutions a practical trial in the various neuroses, &c.

I am, Sirs, yours truly,

Hastings. J. STENSON HOOKER.

LIVERPOOL.

The Assizes: the Judge's Charge.—Important Medico-legal Case.

MR. JUSTICE CAVE commenced the business of the Assizes on July 26th by charging the grand jury. With reference to the case in which Owen Green and Mary Ann Roxburgh were charged with manslaughter his lordship said: "According to the evidence the female prisoner struck the deceased man with the neck of a bottle after it had been broken upon the eye, destroying the sight of the eye and cutting the eyebrow. Under the circumstances it was deemed necessary by the medical men to perform an operation upon the man, sewing up the eyelid, and so on. For that purpose it was thought necessary to give him an anæsthetic. He seemed to be a proper subject for the administration of an

[1] A paper read before the American Institute of Electrical Engineers, Niagara Falls, N.Y., June 27th.

Digitized by Google

anæsthetic, but during the course of the operation he appeared to be in a fainting condition and ultimately died. He died under the anæsthetic in a way which the medical men were unable to account for. No doubt in a case where a person knocked another down and rendered an operation necessary, and during that operation the person died—not from the direct result of the blow itself, but from other causes which were hard to explain—he had no doubt in such a case it might be contended with much probability that the person who struck the blow was liable for the consequence. But it was hardly desirable in a case like that, unless there was grave necessity, to let the case rest upon a principle of that kind. If the grand jury thought there was a *primâ facie* case against the woman he would have a bill sent up charging her with wounding with intent to do grievous bodily harm, which would leave the cause of death an open question."

High Rate of Infant Mortality.

At the last meeting of the Health Committee Dr. Hope reported an increase in the mortality, and stated that it was almost entirely owing to deaths of very young children, no less than 60 per cent. of the total being under five years of age. The earlier the period of life the higher the mortality had been. This lamentable loss of infant life was largely, if not entirely, owing to injudicious feeding. So far as inquiries could ascertain the fact, there was no structural sanitary defect in any of the houses where the deaths had taken place. In a considerable number there was evidence of domestic neglect and dirt, and in a great bulk there was evidence of improper feeding. Those matters were exceedingly difficult for a sanitary authority to deal with, inasmuch as they depended upon the amount of care and intelligence exercised by the mothers. In accordance with a suggestion from the committee he had caused a memorandum to be very freely distributed showing what could be done to prevent this mortality among children, and it was hoped some attention would be given to it. Of course, there were cases in which the evidence of neglect and improper feeding were entirely absent. This high rate of infant mortality was not peculiar to Liverpool by any means; every great city had its proportion of it. In other respects the health of the city was gratifying. Other forms of zymotic disease were markedly below the average. The one solitary case of small-pox in the city was imported from America. The number of patients in the hospital was low.

(FROM OUR OWN CORRESPONDENT.)

Proposed New City Hospital for Edinburgh.

AS was mentioned in THE LANCET a site had been provisionally selected by the Lord Provost and others at Craiglockhart as suitable for the proposed new city hospital. The site was inspected by the medical officer of health, and Dr. Claud Muirhead, the consulting physician to the City Hospital, and adversely reported upon. This report came up before the last meeting of the town council and led to some discussion; but the Lord Provost, with great wisdom, decided to abandon all thought of fixing upon the site thought of. He avowedly did this because of the medical report, although he was evidently disposed to think the medical experts were too decided in their disapproval, yet, as he said, it would not do to go forward in the face of such an adverse opinion.

Water of Leith Sewerage Commission.

The annual inspection of the works for the purification of the water of Leith was made last week. The various works in connexion with it were inspected, and much satisfaction was expressed with the result. The essential feature has been the construction of a great drain by means of which substances which were formerly discharged into the stream are now carried away. There are of course reservoirs and settling tanks in connexion with the scheme, the whole having cost somewhere about a quarter of a million of money. So thoroughly has the work been done that the stream promises to be a good trouting stream in the not far distant future.

The Professional Examinations in Edinburgh.

It may be of interest to note that the success of the lady students at the First Professional Examination has created considerable interest. The lady who appeared for the second professional examination has also passed.

(FROM OUR OWN CORRESPONDENTS.)

The Battle of the Clubs at Cork.

THE death of Dr. O'Sullivan, induced as it was by overwork, has caused consternation amongst the Cork clubs. Last week one of the lodges of Oddfellows held a meeting to consider the situation, and about thirty members attended. A proposition was made that the terms of the Cork profession be accepted. The paid secretary of the lodge strenuously opposed the proposal. A poll was taken, and it was found that there were four for and seven against the resolution. The remainder, forming the great bulk of the meeting, were so unsettled in their opinions that they actually declined to vote. This looks very like the beginning of the end. There is no doubt that every day the legitimate members of the clubs are coming to realise that they are standing in their own light by supporting the unreasonable demands of the merchants, the bankers, and the builders to be treated on the same terms as the clerks, the artisans, and the labourers. Many of the well-to-do club members have not hesitated during the present contest to call in the assistance of the local practitioners and pay them the ordinary private fees, but unfortunately the poorer members are not in a position to do so, and several of them naturally wish for a larger field to select from when appointing a club officer. Some of the more ardent spirits will no doubt endeavour to have the appointments held by Dr. O'Sullivan distributed amongst the three remaining imported medical men; but it remains to be seen, if such should occur, whether the latter will be physically capable of discharging the increased duties. Indeed, it is freely rumoured in professional circles—and I have reason to believe it is quite true—that club practice in Cork is at present so harassing and exacting that the health of one of the three club officers is already so seriously damaged that the unfortunate young man has been obliged to decide on leaving Cork within the next month. A deputation from the Cork profession has proceeded to London for the purpose of representing to the meeting of the British Medical Association the exact state of affairs in Cork, and to impress on the profession at large the importance of a combined effort to strenuously oppose the ever-growing abuses connected with club practice. I have already said, and I repeat it, that to secure success the Cork men need only persist in working as energetically as they have done, and continue to preserve the splendid discipline they have already exhibited

Sir W. Thornley Stoker.

A committee of medical men has been arranged for the purpose of entertaining Sir W. Thornley Stoker, President of the Royal College of Surgeons, at dinner, in congratulation upon his receiving the honour of knighthood; but as the present period of the year is not suitable for such functions it has been agreed to defer any practical outcome until the end of October.

Meath Hospital and County Dublin Infirmary.

Mr. R. Glasgow Patteson, M.D., F.R.C.S., has been appointed surgeon to the above hospital, in the room of the late Sir George H. Porter, Bart.

The Epileptic Wards of the Belfast Union Infirmary.

In THE LANCET of July 27th I gave an outline of the suggestions made by the inspector of the Local Government Board arising out of an inquiry held in Belfast as to the death of a man in the lunatic department of the union infirmary. A committee of the Belfast Board of Guardians, appointed to consider the inspector's report, advise that copies of the paragraphs in it relating to the diagnosis of disease, and to the desirability of consulting the visiting medical officers before sending a patient to the epileptic wards of the lunatic department, be sent to the resident medical officers, and that they be informed that the Board is of opinion that such consultation is necessary. They also recommend that some epileptics be separated from the other inmates of the lunatic department, and that separate recreation grounds be provided for them. Further, they are of

Digitized by Google

opinion that a committee should be appointed to consider how this could best be carried out, and to report what arrangements could be made for providing a separate room for the examination of patients on admission. They recommend that apartments be provided for accommodation of patients suspected of lunacy, in which they may be kept under observation until the nature of the case becomes apparent. They also recommend that when a patient is admitted on a medical certificate the resident or visiting medical officer should be handed such certificate.

Carnlough Water and Sewerage Scheme.

At a special meeting of the Larne Board of Guardians, held on July 24th, plans were submitted by the engineer in reference to the water and sewerage scheme, which were approved of; and it was decided to forward them for inspection and approval to the Local Government Board. Carnlough is one of the most desirable summer health resorts in Ulster, and new water and sewerage schemes will be a very important improvement.

Death of Brigade-Surgeon Coates, M.D.

Great regret is felt in Belfast by the news just received of the death of a distinguished Ulster man on July 10th at Calcutta—Brigade-Surgeon John M. Coates, M.D. He was born at Portaferry, county Down, in 1832, he entered Queen's College, Belfast, as a scholar in 1851, and in 1855 graduated M.D. in the late Queen's University of Ireland. The following year he entered the Indian Medical Service by competition, and was sent at once to Bengal and passed through the Mutiny of 1857. After going through the usual term of active regimental service he was appointed Sanitary Commissioner of Bengal, and afterwards he became President and Professor of Medicine in the Calcutta Medical College, an onerous and responsible post which he occupied for several years. In 1890, having had two extensions of service in the two positions he occupied, he retired with the rank of Brigade-Surgeon. He was a most distinguished student of the Belfast Medical School, and acquired an extremely high reputation on the eastern side of India. As a consulting physician his services were in great request and his opinion was very highly valued. Indeed, he enjoyed a very enviable Indian reputation both as a physician and as a professor in the Calcutta medical school, and he was personally a great favourite both with Anglo-Indians as well as with the natives. Some time ago he was urgently telegraphed for to go to India to attend a Rajah who had the utmost confidence in his skill. He went out at once to Calcutta, and it was while there that he contracted cholera from which he died. Brigade-Surgeon Coates was married to the daughter of a well-known and respected Belfast merchant, who survives him. A son is in medical practice in London, and some of his daughters are married in India. Brigade-Surgeon Coates was a man who by sheer ability and force of character rose to a very high position in India. Indeed, at one time he was offered the appointment of Surgeon-General of Bengal, which, however, he declined. By his death Queen's College, Belfast, loses one of her most distinguished alumni.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The International Congress of Otology.

SCIENCE has her "autumn manœuvres"—for such undoubtedly are the coming *réunions* of *savants*, medical and other, for the review of their work during the last twelvemonth or more, and for the exposition and discussion of innovations in the perennial warfare against ignorance, disease, and death. The present year is exceptionally prolific in these assemblages—not the least interesting among them being that which will meet in Florence on Sept. 23rd, when an international congress will be held at which the leading aural surgeons of Europe and America will assist at a "march past" of otological medicine. The last congress of the kind, it will be remembered, took place in 1888 at Brussels, at the close of which it was unanimously agreed that its successor—the fourth in the series—was to be held in the Tuscan capital. Dr. Vittorio Grazzi, Professor of Aural and Laryngeal Medicine in the University of Pisa, is to preside, and among those already announced to take part in the proceedings are Dr. Adam Politzer (who holds the chair of Otology in the Vienna School), Dr. Gellé of Paris, Dr. J. Barr of Glasgow, Dr. Gradenigo of Turin, and a number of well-known aural surgeons in both hemispheres.

"La Clinica Moderna."

Professional, equally with political, journalism was long at a low ebb in Italy, reflecting all too faithfully the outcome of those obscurantist forces which dominated the peninsula. Now the national "risorgimento" includes the academic, the scientific, the literary, as well as the political and social life of the people, and conspicuous among its products is the improved character of its medical journalism. The "Policlinico," due to the inspiration of Baccelli, has now a worthy compeer in the "Alta Italia," published at Milan by the enterprising house of Bicchi. Its name betokens its object—"La Clinica Moderna"—and its staff, seventy in number, is drawn from the clinical teachers and *privat-docents* of all the Italian schools. Full reports of university lectures on the practical side of medicine are given from time to time—the subjects being medical, surgical, obstetric, dermatological, ophthalmic, and psychiatric, according as they emerge into special prominence under special circumstances. The tenth *fascicolo* is now before me, and its features are original and attractive enough to explain the announcement that has just reached me that the Munich school are projecting a journal similar in character and on similar lines.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Medical Insurance.

THE Austrian Medical Chambers are at present considering the details of an insurance scheme, according to which every medical man will be expected to take measures entitling him to an annuity of £40, commencing on the attainment of his sixtieth year. From this obligation those medical men will be exempted who hold appointments giving them a claim to a pension amounting to the above sum, as well as those who are above forty years of age or are already insured. A fund is also to be founded for the benefit of the widows and orphans of medical men; the widows' pensions are to be £40 a year, and the orphans' pensions £4 a year for each child.

The Antitoxin Treatment of Diphtheria.

Among the recent contributions of Austrian physicians to the literature of the above subject is a noteworthy lecture by Dr. Jakubowski, professor of pædiatrics in Cracow, who gave details of 75 cases and declared himself a firm believer in serotherapy. Monti has treated 25 cases, among which 1 died, but Gnandinger, on the other hand, has reported on 27 cases, with a death-rate of 40 per cent., and he accordingly does not prefer this to other methods of treatment. Jakubowski employed all the various kinds of serum, differing from one another both in chemical composition and in the proportion of active antitoxin present. Roux's serum and Aronsohn's serum come up to that of Behring II. For the purpose of better preservation Roux adds camphor, Behring 0·5 per cent. of carbolic acid, Aronsohn 0·4 per cent. of cresol, and Bujwid (in Cracow and Warsaw) chloroform. Among the 75 patients of Jakubowski, 38 were treated with Behring's serum, 14 with Bujwid's, 20 with Roux's, and 3 with Aronsohn's. The injections were made on the thigh, and the punctures were covered with iodoform gauze and sticking-plaster. As the originator of the serum treatment considered it to be efficacious only in the case of diphtheria caused by Löffler's bacilli, bacteriological examinations were made and the results recorded. In primary diphtheria with greyish coating on the tonsils and the palatine arches Löffler's bacilli are certain to be found, but when the coating is yellow, staphylococci and streptococci are the prevailing forms, and the most efficiently conducted serum treatment is without success. In 17 per cent. of the cases Jakubowski observed urticaria and erythema. The former appeared three or four days after the injection and disappeared after three days; erythema showed itself on the trunk in the form of reddish spots, and was accompanied by fever and weakness of the heart. Three patients complained of pains in the joints. All these symptoms are to be regarded as consequences of some unknown toxines contained in the serum, and the physician, therefore, in the case of slight diphtheria, has to decide whether he will incur the risk either of

Digitized by Google

producing complications or, on the other hand, of deferring the use of antitoxin till a time when it is ineffectual. There are two methods of investigation which prove the efficacy of serotherapy—statistical returns and the comparison of the course of the disease before and during treatment. Widerhofer arranged the following scale: (1) slight diphtheria with good prognosis; (2) serious cases with doubtful prognosis; (3) very grave cases; and (4) necessarily fatal prognosis. He has, however, had under his care sixteen cases of the fourth form and ten among them have recovered. On the other hand, Monti distinguished: (1) slight cases with fibrinous coating; (2) grave cases with parenchymatous infiltration; and (3) gangrenous diphtheria. Jakubowski divides the cases into those where the morbid process is limited to the pharyngeal mucous membrane and those where diphtheria is complicated with croup. The course of slight diphtheria is modified by antitoxin; the false membranes are loosened and the progress of the diphtheritic infiltration is stopped. Paralysis and cardiac debility were not influenced by the remedy. In the case of croup and obstruction of the larynx antitoxin by itself is not sufficient, but intubation and tracheotomy are to be performed. Serotherapy relieves the difficulty of breathing; the patients expectorate a serous purulent sputum, and auscultation shows moist crepitant râles, whereas dyspnœa, cyanosis, and dry crepitant râles have hitherto been the rule. The average mortality has fallen from 50 to 32 per cent. Although Jakubowski has not obtained such good results as some other physicians, he nevertheless recommends the antitoxin treatment as being by far the most efficacious of all the methods proposed against diphtheria. Neudörfer has published in the *Wiener Medicinische Wochenschrift* his views on the pathogenesis and treatment of diphtheria. He asserts that even the gravest cases which have been given over by experienced physicians not uncommonly recover without any remedy, because nature limits the consumption of oxygen and thereby enables life to be maintained on a reduced supply. Without going so far as to agree with Caron, who exclaimed: "Hors la trachéotomie point de salut pour les croupalisés," Neudörfer nevertheless attributes to this operation a great importance, for by it the inspiration and consequent absorption of oxygen are increased in comparison with breathing through the nose. In his opinion tracheotomy may be performed even after respiration has ceased, provided that the heart still pulsates even feebly.

BEQUESTS AND DONATIONS TO HOSPITALS.—The committee of the current year's collections of the Liverpool Hospital Sunday and Saturday Funds has distributed among the Liverpool charities the following sums: Royal Infirmary, £2438; Royal Southern Hospital, £1696; Northern Hospital, £1484; Liverpool Dispensaries, £742; Infirmary for Children, £636; Stanley Hospital, £530; Eye and Ear Infirmary, £477; Consumption Hospital, £318; Convalescent Institution, £212; Hospital for Women, £212; St. Paul's Eye and Ear Hospital, £212; Cancer Hospital, £106; Home for Incurables, £106; Dental Hospital, £26 10*s.*; St. George's Hospital for Skin Diseases, £26 10*s.*—Mr. John Todd, late of Swanland Hall, in the East Riding of Yorkshire, has bequeathed £300 to the Hull Royal Infirmary, and £100 to the Hull and Sculcoates Dispensary.—The late Mrs. Church Dixon, of Govan-hill, Glasgow, has bequeathed £500 each to the Grosvenor Hospital for Women, London, and to the Belgrave Hospital for Children, Gloucester-street, London.—The late Mrs. Fraser, widow of the late Bishop of Manchester, has bequeathed £2000 to the Manchester Cancer Hospital, and £1000 each to the Manchester infirmary and the Radcliffe Infirmary, Oxford. The distribution of this year's collection for the Birmingham Hospital Saturday Fund to the medical charities is as follows:—General Hospital, £3050; Queen's Hospital, £2025; General Dispensary, £1150; Children's Hospital, £750; Eye Hospital, £500; Birmingham and Midland Counties Sanatorium, £225; Women's Hospital, £400; Lying-in Charity, £125; Orthopædic Hospital, £250; Ear and Throat Hospital, £100; Dental Hospital, £50; Skin and Lock Hospital, £225; Jaffray Suburban Hospital, £550; and Moseley Hall Convalescent Home, £100.—The late Mr. Edmund White of Bath has bequeathed £100 to the Royal United Hospital, Bath, and £500 to the Sanatorium, Weston-super-Mare.—The executors of the late Mr. Benjamin Waters, through their solicitors, have handed to the treasurer of the Royal Infirmary, Newcastle, £9595 2*s.* 9*d.*, being the amount the institution is entitled to under his will after deducting legacy duty.

THE

BRITISH MEDICAL ASSOCIATION.

MEETING IN LONDON.

THE sixty-third annual meeting of the British Medical Association commenced its work in London on Tuesday last, under the distinguished presidency of Sir John Russell Reynolds, the President of the Royal College of Physicians of London.

A dinner given by the President, then President-elect, of the Association on Monday evening may be said to have gracefully ushered in the proceedings of the Association, though the entertainment was in no sense official. About 100 guests sat down to dinner with Sir J. Russell Reynolds at the Buckingham Palace Hotel, and the company comprised a remarkable number of distinguished men in the profession, besides the President's personal friends, medical and lay. The speeches, which were quite informal and commendably brief, were made by the host, and by Dr. Ward Cousins, and Sir Richard Quain, whilst Dr. Frederick Roberts was responsible for the musical reception of the toast of Sir J. Russell Reynolds' health.

A large number of members of the Association assembled at St. Paul's Cathedral at half-past eleven on Tuesday morning, to listen to a special sermon which was preached by his Grace the Archbishop of Canterbury. Upon the somewhat transcendental text, "And he showed me a pure river of water of life, clear as crystal, proceeding out of the throne of God and of the Lamb," his Grace founded an eloquent comparison between the work of the physician of the body and that of the physician of the soul, and, pointing out the similarity between the workings of accurate science and moral law, concluded by emphasising the necessity for reverence in the presence of the stupendous secrets of Nature. This reverence, combined with true sympathy, formed, he considered, the true Religio Medici.

At the first general meeting, which was held in Exeter Hall in the afternoon, Sir J. Russell Reynolds was inducted into the chair by the retiring president, Dr. E. Long Fox of Bristol. This meeting was considered to be the largest annual general meeting ever held, upwards of 1,000 members having been present. Some of the business before the meeting was of a decidedly contentious character, and considerable heat was engendered in its discussion.

The motion down in the name of Mr. Lawson Tait, protesting against the Midwives Registration Bill, was worded as follows:—

"That we, the members of the British Medical Association, while anxious to improve the training and supervision, and, if need be, to support a practical scheme for the registration of medical, surgical, and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical or surgical or midwifery practitioners other than those recognised under the Medical Act, 1886, as now existing. We protest against the Midwives' Registration Bill because it proposes to establish a class of midwifery practitioners who would be very incompletely trained in midwifery, and entirely uninstructed in medicine, surgery, and pharmacy—a matter of supreme importance in midwifery practice. We therefore instruct the council and the Parliamentary Bills Committee to use every means to oppose any Bill which proposes to give to persons registered under it power to conduct, on their sole and independent responsibility, any midwifery practice without the guarantee of a complete curriculum and qualification. That this association recommends a sum not exceeding £1000 be expended for the purpose of opposing any such Bill."

It was carried by a large majority, whose attitude left no doubt as to the sincerity of their votes.

On Tuesday evening there was a reception given by the metropolitan members of the Association at the Imperial Institute. Sir William and Lady Priestley, supported by the reception committee, consisting of Dr. and Mrs. W. Miller Ord, Dr. Church, Dr. Holman, Mr. Andrew Clark, Mr. W. J.

Digitized by Google

Walsham, Mr. Rickman J. Godlee, Dr. Sansom, and Dr. Bridgwater, received the company in the vestibule.

The programme was embellished with a portrait of Sir Charles Hastings, the founder of the British Medical Association. Arrangements were made for the reception of 5500 guests, and the Great Hall of the Imperial Institute was full, many having to stand, when shortly after nine the President, accompanied by some of the members of the Council. took up his position on the platform to deliver his address. The acoustic properties of the hall did not permit of the voice of the lecturer being heard all over the auditorium, and towards the latter part of his brilliant address a band started to play in the gardens, which prevented many from hearing his concluding remarks. But all those whose position in the hall—coupled with the fact that Sir J. Russell Reynolds' voice, though very clear, was not very loud—precluded them from hearing the address, are strongly recommended to peruse it in our columns, where it is printed in full (p. 245). After the delivery of the Presidential Address the company adjourned to the gardens of the Institute, which were brilliantly illuminated, but overcrowded to inconvenience. Herr Eduard Strauss conducted his orchestra, which performed a charming selection of music. The band of the West London Rifles was also in attendance.

On Tuesday afternoon the Baroness Burdett-Coutts and Mr. Ashmead-Bartlett-Burdett-Coutts extended the ever-ready and profuse hospitality of Holly Lodge, Highgate, to the members of the Association. The beautiful grounds of the best-known villa in Greater London were looking their best, and the members, who were entertained simultaneously with the members of the International Geographical Congress, spent a thoroughly pleasant afternoon. The Baroness Burdett-Coutts, supported by her husband, received her guests personally.

It is perhaps fitting that the oldest hospital except one in the British Islands should offer hospitality outside the usual official kind to the members of the British Medical Association, and the luncheon party given by the staff of St. Bartholomew's Hospital on Wednesday, July 31st, was a brilliant example of what such a function should be. About three hundred guests were there, the place of meeting being the great hall of the hospital, its walls hung with portraits of former physicians and surgeons. The portrait of the patron saint is at one end and at the other that of Henry VIII., the two recalling a remark of Burke, aptly quoted in Dr. Norman Moore's little brochure on the history of the hospital, "that there were temples dedicated in India to Brahma and Vishnu, the good and guardian deities, and to Rudor, the evil spirit, whose unwearied enmity and malign influence they deprecated." All the members of the staff, with the notable exception of Sir James Paget, who was unavoidably absent, were there, and among the distinguished guests were most of the prominent metropolitan and provincial medical men. Among the foreign guests were Professor Stokvis, Dr. Apostoli, Dr. Ottolinghi, Professor Mosso, Professor Pozzi, Professor Lazarewitch, and Dr. Fraenckel. The Presidents of the various Sections of the Association were present, and last, but not least, Surgeon-Captain Whitchurch, V.C. Speeches and toasts were, as became the occasion, few. Mr. Thomas Smith, an admirable chairman, proposed first the health of the Queen and then that of the visitors, especially Surgeon-Captain Whitchurch. Professor Stokvis, speaking excellent English, replied on behalf of the foreign visitors, and elicited much applause by saying that the history of St. Bartholomew's was the history of medical science. Dr. Clifford Allbutt spoke on behalf of the Association. Mr. Christopher Heath replied for the surgeons, and Surgeon-Captain Whitchurch, in a few modest and well-chosen words, spoke for himself. He was afterwards chaired round the square by a cheering crowd of students. After lunch the visitors inspected the various departments of the hospital, special interest being shown in the instruments and fittings of the electrical department, demonstrated by Dr. Lewis Jones. Altogether it was a very pleasant and successful gathering, and the staff of the hospital have every reason to congratulate themselves.

The address with which Dr. Wilks opened the proceedings of the section of Pathology and Bacteriology on Wednesday was characteristic of its author in the width of view and robust common sense that were its features. It is calculated, too, to do good service by recalling us for a time from the more recondite problems which face the pathological investigator to the root principles of morbid action and the destiny of morbid processes. For the whole tenor of his instructive remarks was to the effect that the destructive changes wrought by diseased action in tissues and organs proceed hand-in-hand with reparative and regenerative processes, whereby nature arrests morbid activities and tends to preserve vitality threatened by disease. Dr. Wilks did well to prove in so convincing a manner that the study of morbid anatomy itself is by no means exhausted, and we look forward to the practical development of his thesis in the observations of pathologists upon the conservative powers of the organism attacked by structural lesions.

Sir William Priestley's presidential address in the Obstetrical and Gynæcological Section of the British Medical meeting on Wednesday deserves to be carefully perused, as it contains the results of a long experience, and gives some warnings not by any means untimely considering the surgical ardour which characterises so much of the gynæcology of the present day. Sir William Priestley reviewed the many fashions which had prevailed during his professional career, from the time when nearly every pelvic symptom was imputed to so-called ulceration of the cervix before a careful study of the pathology of the condition was made, and when the very heroic measures were persistently employed for its cure. He referred to some of the more recent procedures, such as the stitching of the cervix, advocated especially by many American gynæcologists in nearly every woman who had borne a child, and to the fashion, fortunately moderating, in this country at least, of excision of the ovaries and tubes for merely symptomatic conditions. He deprecated the building up of a reputation by the publication merely of a long list of statistics of cases selected for operation which might not always be indicative of real progress, but rather of the reduction of practical surgery to a mere handicraft, and not a noble art founded on a true scientific basis.

Mrs. T. Seymour Tuke gave a garden-party which was numerously attended by the members and their friends on Wednesday afternoon at Chiswick House, Chiswick.

On Wednesday afternoon the members of the Association were invited to be present at a promenade concert held at the gardens of the Royal Botanic Society in the inner circle of Regent's Park. To those who attended it must have seemed wonderful that such a beautiful spot should be almost entirely unknown to Londoners, but without doubt the exclusiveness of the society has enabled it to preserve for its precincts an air of privacy which greatly enhances their loveliness. On the same evening, fortunately in perfect weather, the Royal Botanic Society gave a special evening *fête* to the members of the Association, the grounds being illuminated for the purpose. An exhibition was held of

Digitized by Google

medicinal plants in a marquee, and selections of music were performed at intervals during the evening.

There have been complaints in several quarters of the lack of hospitality shown by the City to the Association, but we hope that it is now clearly understood by London guests that the Corporation have not been wanting in courtesy. Congresses in London are numerous, and distinctions would be invidious. We, as medical men, might rightly hold that a medical congress should stand on a separate footing; but we cannot be surprised that the City has not seen the situation in the same light. Moreover, public entertainment of large bodies of men is expensive, and the commonest cry against the City of London is that it is lavish. While on the subject of hospitality we cannot refrain from calling the attention of the authorities of the British Medical Association to a small omission in their arrangements. They have omitted to give complimentary tickets to the scientific professors of Kings College, whose rooms they are occupying. Professors of Physics, Chemistry, Engineering, Arts of Construction, &c., might have been glad of an opportunity of hearing some of the technical papers, although they obviously could not belong to a medical association. We hope that, ere this, the oversight has been remedied.

A Masonic smoking concert was held on Thursday night at the Portman Rooms, Baker-street, the invitations being given by the Æsculapius Lodge and Chapter (No. 2410) to provincial and foreign medical brethren.

We desire to congratulate Dr. Tirard and his coadjutors on the admirable manner in which the Museum of Exhibits has been organised and the great freedom from objectionable elements that is noticeable in the catalogue. To those who know what such catalogues are apt to be, the fact that this one is free from puffery, either direct or indirect, will convey our impression that the editing has been drastic and fitting.

The business at the second general meeting was very interesting to the profession at large by reason of two motions of instruction to their Council passed by the Association. The first, the bearing of which upon the Bill for the Registration of Midwives will be immediately recognised, instructed the Council to approach the General Medical Council with a view to making the final examination of our students in midwifery more practical by greatly increasing the number of confinements to be attended. The second instructed them to take steps to have a Bill introduced into Parliament to increase the number of direct representatives upon the General Medical Council.

On Thursday afternoon there was an excellent choice of entertainment—a garden party given by Dr. Langdon Down at Normansfield, Hampton Wick; a garden party at the Hospital for Sick Children, Great Ormond-street, where Mr. J. H. Morgan was the efficient host; a garden party at St. Thomas's Hospital; and a smoking conversazione at Mr. Hutchinson's Clinical Museum, 1, Park-crescent, Regent's-Park. All were well attended and thoroughly enjoyable. The annual dinner of the Association was held in the Queen's Hall, Langham-place, on the same evening.

THE GENERAL MEETINGS.

THE FIRST GENERAL MEETING.

THE first general meeting was held in Exeter Hall, where a large number of members assembled, on Tuesday, July 30th.

The Secretary having read the minutes of the last meeting, Dr. LONG FOX, the retiring President, thanked the members of the Association for the high honour they had done him in permitting him to occupy the chair during the past year, and expressed to them and to the Council his high appreciation of the great kindness they had personally shown him. In conducting Sir J. Russell Reynolds, President of the Royal College of Physicians (the President-elect), to the chair, Dr. LONG FOX said the name and life-work of Sir J. Russell Reynolds were well known not only to the medical profession, but throughout the whole world, and he need not say how delighted they all felt in having him for their President.

Sir J. RUSSELL REYNOLDS, on taking the chair, said he could find no words in which to express his thanks to Dr. Long Fox for the kind manner in which he had introduced him to the meeting. The honour which had been conferred upon him was a great one, and he was delighted to accept it.

Sir WILLIAM HINGSTON proposed a vote of thanks to Dr. Long Fox, which concluded with the words, "that he be and is hereby elected a Vice-president for life." This was seconded by Mr. J. HUGHES HEMMING and carried with acclamation.

Dr. LONG FOX gracefully returned thanks.

Dr. WARD COUSINS (President of the Council) moved the adoption of the report for the year ending December, 1894. He referred to the great progress which the Association had made, and reviewed the work done during the year, dwelling in particular upon the necessity for amendment in regard to the Medical Acts, the need for reform in the matter of dealing with inebriates, and the examination of school children. Adverting to the losses which the Association had sustained by death, he paid a graceful tribute to the memory of Mr. Arthur Durham and Dr. Withers Moore.

Dr. DOUGLAS called attention to the usual delay in presenting the report.

Dr. WARD COUSINS assured Dr. Douglas that the matter should be taken into consideration in the future.

Matters relating to the conduct of the Journal were then discussed by Mr. COLIN CAMPBELL, Dr. RENTOUL (who thought the Association should financially help Mr. R. B. Anderson, who was fighting a battle for the profession), Mr. GARRETT HORDER, Surgeon-Major INCE, and Mr. GANT. The motion, which had been seconded by Mr. BUTLIN, was then carried and the report duly adopted.

The interim report of the committee appointed to consider complaints of general practitioners was then discussed, when the following rider was proposed by Mr. LAWSON TAIT: "That we, the members of the British Medical Association, whilst anxious to improve the training and supervision and, if need be, to support a practical scheme for the registration of medical, surgical, and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical or surgical or midwifery practitioners other than those recognised under the Medical Act, 1886, as now existing."

Mr. COLIN CAMPBELL seconded.

Surgeon-Major INCE had the following resolution on the paper, but on the general request of the meeting it was withdrawn: "That in the interests of the mothers of the United Kingdom the regulation of midwives, after suitable training and examination, is a subject deserving the early and careful consideration of the Legislature, and in that consideration it is equally desirable that the legitimate rights and privileges of duly qualified medical practitioners should not be overlooked."

After a few words from Mr. VICTOR HORSLEY, Dr. MURDOCH CAMERON proposed: "That legislation on the subject of the registration and training of midwives should receive the support of the British Medical Association." Dr. HAYWARD, Sir WALTER FOSTER, Dr. CULLINGWORTH, Mr. WHEELHOUSE, Dr. WOODCOCK, and Dr. SCHARLIEB spoke, and the amendment was then put to the vote and lost. Mr. LAWSON Tait's rider was then carried by a large majority.

Dr. WELSFORD proposed, Dr. J. F. BULLAR seconded, and Mr. GEORGE BROWN supported the following resolution, which was carried: "That it is to the interest of the public and of the medical profession that the Council of the British Medical Association should take power and authority to protect both the individual and collective interests of the medical profession, and that the Council be requested to take such steps as may be necessary to enable it to actively undertake these duties, and that the funds of the Association be used for this purpose."

Dr. BEDFORD FENWICK moved: "That, in the opinion of this meeting, it is expedient that an Act of Parliament should as soon as possible be passed providing for the registration and education of medical, surgical, and obstetric nurses; and the Council of this Association are therefore

Digitized by Google

requested to consider this matter and to take such measures as may seem to them advisable to obtain such legislation." This was seconded by Dr. JOHN BROWN and carried. The meeting then adjourned.

SECOND GENERAL MEETING.

The second general meeting was held at Exeter Hall, on Wednesday afternoon, when Sir WILLIAM BROADBENT delivered the address in Medicine, which we print in full in our present issue. Upon its conclusion, Dr. PAVY said that he felt it a pleasurable privilege to be called upon to propose a vote of thanks to Sir William Broadbent for his address. All would admit that the deliverer of the address had been most wise and most happy in the subject he had selected, and they had listened to a learned address which could only come from a mind of a high order. The address was worthy of the man who had delivered it.

Dr. CUMING seconded the motion, which was carried unanimously.

Sir WILLIAM BROADBENT briefly returned thanks.

The business standing over from the previous day was then considered.

Mr. VICTOR HORSLEY moved the adoption of the Parliamentary Bills Committee report.

Dr. WOODCOCK seconded the motion.

A motion by Dr. LOVELL DRAGE, seconded by Dr. R. R. RENTOUL, that the Council should be instructed to petition the General Medical Council to recommend that no student be admitted to his final medical examination until he presents a certificate showing that he has personally conducted at least thirty confinements under the direct supervision of a registered medical practitioner, was carried. The motion also included instruction to the Council to take immediate steps to have Section 20 of the Metropolitan Poor Act, 1869, repealed, which prevents workhouse infirmaries from being used for the clinical instruction of medical students in practical midwifery, while pupil midwives are now admitted; and also to petition the committees, medical staffs, and, if need be, the subscribers to the City of London Lying-in, the British Lying-in, and the Clapham Maternities to withdraw their rule which excludes male medical students from clinical instruction at these hospitals, seeing that these are now used by pupil midwives.

A rider to the report was proposed by Dr. R. R. RENTOUL, supported by Sir WILLIAM FOSTER and Mr. WHEELHOUSE, which set out the reason why the Association should instruct its Council to take immediate steps to have a bill introduced into Parliament providing that the registered medical practitioners in England and Wales be empowered to elect five additional direct representatives, the practitioners resident in Scotland one additional direct representative, and the practitioners resident in Ireland one additional direct representative to the General Medical Council."

This also was carried, and after the reports of various committees had been passed the meeting adjourned.

THIRD GENERAL MEETING.

The third general meeting was held on Thursday in Exeter Hall, at 3 P.M., when Mr. Hutchinson delivered the Address in Surgery, which we publish in full. The Stewart Prize, awarded to Brigade-Surgeon-Lieutenant-Colonel D. D. Cunningham, F.R.S., was received for him by Mr. Francis Fowke, the General Secretary of the Association.

THE SECTIONS.

The work in all the Sections commenced on Wednesday, July 31st, with the various Presidential Addresses. Most of the Sections were well attended, and the subjects set down for discussion elicited some fairly general and practical debating.

MEDICINE.

Dr. PAVY, the President of the Section, having briefly introduced the subject, called upon Dr. Sidney Martin to open a discussion on

Diphtheria and its Treatment by Antitoxin.

Dr. SIDNEY MARTIN said:—There have been numerous remedies which have been used in the treatment of diphtheria, some of which—local applications—have for their object bacteri idic action on the membrane or a loosening action by which the membrane is made to separate more easily. Others, again, have been vaunted for their general action—that is, for their effect in counteracting the general symptoms of the disease. In no instance, however, in which a drug has been so extolled is there evidence that there has been an effect on the general symptoms of the disease, either in relieving the bodily depression, in reducing fever, or in relieving or preventing the occurrence of broncho-pneumonia or paralysis and the extension of the disease to other parts. When, therefore, a remedy is introduced, the recommendation of which is based on well-established scientific experiments, its application in the treatment of the disease, and especially its effect on the symptoms of the disease, require close examination, not only at the bedside, but in the laboratory. The recommendation of antitoxin in the treatment of diphtheria is based on the results of a study of the pathology of the disease, and it is necessary that this should be clearly understood before the value of the remedy can be in any way gauged. Diphtheria may be defined as the membranous inflammation of a mucous membrane, usually of the respiratory passages, due to the invasion of the bacillus diphtheriæ, which does not enter the body, but forms poisons in the membrane which produce general symptoms of fever, &c., as well as a palsy due chiefly to a nerve degeneration. One point I should like to insist upon in this definition—namely, that the presence of nerve degeneration is *the* pathological test of diphtheria. There are other membranous inflammations of the throat due to micro-organisms, but diphtheria is the only one which leads to nerve degeneration. Similarly the pathological test of the bacillus is not that it produces death, but that it produces nerve degeneration. The pathological test of the poisons found either in the bodies of patients dead of diphtheria, or formed by the bacillus diphtheriæ outside the body, is not that they produce death (because many poisons have a similar effect) but that they produce nerve degeneration. It is not meant by this that there are no other poisons which produce nerve degeneration, because such are known; but when it is a question of the bacillus diphtheriæ it is nerve degeneration which is the final and most accurate test of its presence. It must be evident that the chemical poisons which are found in diphtheria are of great importance in the present connexion, inasmuch as it is these poisons which the antitoxin has to counteract. Patients the subject of diphtheria die, some from mechanical obstruction by the membrane, some from broncho-pneumonia, but the majority die from the effects of the poison in combination with one of the two first. Such are the deaths which occur from syncope, suppression of urine, "asthenia," and from paralysis. The chemical poisons which are found in patients who have diphtheria belong to two classes—one is found in the membrane, the other is found in the tissues (especially blood and spleen); and the action of these two classes of poison, although similar in some respects, present important points of difference The chemical poison which is found in the membrane may be extracted by treating the fresh membrane with sterile salt solution, diluting and concentrating at a low temperature, dialysing to get rid of the extra amount of salt, and precipitating with alcohol. The alcohol precipitate, after drying, may be dissolved in water. If a small quantity of this precipitate, which is almost imponderable, be injected into the vein of a healthy rabbit the animal will, after a time, show paralysis, which gradually increases in severity; it will waste; it may have diarrhœa, and it will die after a longer or shorter period. At the post-mortem examination extensive degeneration of the nerves is found, associated with fatty degeneration of the skeletal muscles, and—what is of extreme importance—fatty degeneration of the heart. Subcutaneously injected the poison produces a necrosis of the tissue. The characteristics of this poison, therefore, are that it acts in a single dose, and that it reproduces the symptoms and the pathological changes found in diphtheria. It is, so to speak, the chemical representative of the living, infective agent in the membrane, which is the bacillus diphtheriæ. No analysis is possible of this chemical substance in the membrane; but the profound effect which it produces on the body by a single infinitesimal dose would suggest that it belongs to the class of bodies known as ferments.

The poisons which are found in the tissues of patients dead of diphtheria—especially in the blood and the spleen—differ from this poison in the membrane. They are of two kinds, one of which belongs to the class of digested proteids—viz.,

Digitized by Google

albumoses similar in chemical reactions to the albumoses formed in digestion in the stomach and intestines—and the other body found is a non-proteid substance—namely, an organic acid. It may be said of this last substance that, although it produces some nerve degeneration, it does not produce the progressive paralysis or the profound effect on nutrition which is characteristic of the other poisons of diphtheria. The albumoses, on the other hand, have a very characteristic action. Injected intravenously into rabbits they produce in one or two hours a rise of body temperature, which, on the repetition of the dose, frequently lasts several days. They are, in fact, the fever producers in diphtheria. Although it is possible to kill an animal in a few hours by a single dose of the albumose intravenously injected, an event which does not follow the injection of the ferment of diphtheria, yet the characteristic action of the albumoses is only brought out by the injection into the vein of two or three small doses on successive days. When this is done, besides the fever produced the animal shows at the end of a week or ten days slight paralysis, which gradually increases, and which is not infrequently accompanied by severe attacks of dyspnœa, in one of which the animal may expire. Large doses of the albumoses produce great wasting of the body as well as diarrhœa. In the post-mortem examination of animals that have died there are found extensive nerve degeneration and fatty degeneration of the heart, and, after large doses, the fluidity of the blood which is characteristic of death from many different kinds of albumoses. These albumoses differ, therefore, from the poison present in the membrane, not only from the fact that their injection produces an immediate rise of temperature and their repeated injection a continuous fever, but from the fact that they act in producing palsy only in multiple doses. Injected subcutaneously they do not produce a necrosis, but œdema, the extent of which depends on the largeness of the dose given. In some experiments with the albumoses there is no paralysis observable during life, but after the animal is killed, in from four to ten weeks, the nerves are found degenerated in one or other part of the body, showing that the poison had some effect, although the degeneration was not sufficiently extensive to produce symptoms during life. The fatty degeneration of the heart which is a feature of poisoning by albumoses is an effect which is produced by the injection of albumoses formed by other micro-organisms; for example, the bacillus anthracis and some forms of septic cocci; and since these micro-organisms do not produce a toxic ferment, like the bacillus diphtheriæ, it is probable that the fatty degeneration of the heart is ascribable to the action of the albumoses and not to any direct action of the ferment. Both these classes of poisons—that which is found in the membrane and that which is found in the tissues of patients dead of diphtheria—can be formed artificially outside the body by growing the bacillus diphtheriæ in suitable media. The ferment which is present in the membrane—or toxine, as it is sometimes called—is now made by growing the bacillus diphtheriæ in slightly alkaline meat broth containing 2 per cent. of peptone and 0·75 per cent. of salt. When such a solution is inoculated with a pure culture of the bacillus and grown in an incubator while a current of air passes over the surface of the liquid, as in Roux's method, after a month the liquid is found to contain this poison in large quantity. The bacilli are removed by infiltration through a porcelain filter, and the filtrate, which is still alkaline and yellowish or yellowish-brown in colour, contains the greater part of the peptone which was added as well as the poisonous body. This liquid may be obtained of a very high degree of virulence, so that one-fifth of a cubic centimetre, or even one-tenth, injected subcutaneously into a guinea-pig weighing 500 grammes will produce death in thirty-six to forty-eight hours; and this effect of the poison has been taken as a test of its activity. In his earlier experiments Roux separated this poison by carrying it down in the liquid by means of calcium phosphate, and thus obtained a substance which reproduced the symptoms of diphtheria in infinitesimal [illegible] doses. Injected intravenously into rabbits, this toxine, as will be shown presently, not only reproduces the symptoms, but the nerve degeneration, which is the pathological characteristic of diphtheria.

If, instead of growing the bacillus diphtheriæ in broth containing peptone, it is grown in alkaline broth containing 0·75 per cent. of salt, but instead of peptone about 1 per cent. of alkali albumin, the products of the growth of the bacillus are not the same as in the first instance. Alkali albumin is a proteid which is digestible; that is, pepsin or pancreatin in suitable media will tranform it into albumoses and peptone. The bacillus diphtheriæ does the same. It transforms the alkali albumin into albumoses which have the specific action previously described, and forms a small quantity of an organic acid. These albumoses, for example, when injected in repeated small doses into rabbits produce fever, wasting, and sometimes diarrhœa, but chiefly a progressive paralysis, which is associated with extensive nerve degeneration and also fatty degeneration of the heart. For these reasons, therefore, the bacillus diphtheriæ is the cause of diphtheria. It is found in the membrane; it can be separated from the membrane; and when grown in suitable media outside the body it forms poisons which have the same physiological action as those present in the membrane and in the tissues of patients dead of diphtheria, the specific test relied on being the dependence of the palsy on the nerve degeneration. It is these poisons, therefore, which the antitoxin has to counteract. The pathological process in diphtheria must be considered in the following manner. When the membrane is formed the bacilli growing in it, especially near the surface, secrete a ferment which, when absorbed into the body, produce, by acting on the proteids of the body, digestive products, the chief of which belong to the albumose class. It is not that the body is poisoned by a single large dose and then the action stopped (although this may occur in certain cases), but it is that numerous small doses are in the course of the disease absorbed into the system, and are gradually producing their effects.

We will now proceed to discuss the effect of the diphtheritic antitoxin in counteracting the effects of these poisons. The preliminary experiments in this direction have been performed solely on rabbits, the poison alone being injected into one animal and the poison with a certain amount of antitoxin being injected into another, both animals being kept under similar conditions. The effect on the temperature and weight of the animal was observed, as well as the onset of any paralytic symptoms, and a post-mortem examination was made soon after death (or if the animal did not die some weeks after the inoculation) and the heart examined for fatty degeneration and the nerves for the characteristic degeneration. When the antitoxic serum itself is injected in large doses into the venous circulation of an animal it produces no rise of body temperature and no loss of weight. It is, as far as could be judged, a perfectly innocuous substance in the rabbit. The effect of injecting doses of the toxine in one animal and a dose of toxine mixed with a certain proportion of antitoxin in another is seen in the following experiment. The toxine was prepared by Roux's method, and was formed by the bacillus diphtheriæ growing in 2 per cent. of peptone broth for one month. The virulence of the solution may be gauged by the fact that one-tenth of a cubic centimetre, subcutaneously injected, killed a guinea-pig weighing 500 grammes in less than three days. In this experiment each of two healthy rabbits received 0·5 cc. into the vein of the ear, but in one 0·3 cc. of antitoxin was added. During the first day following the injection there was practically no effect on the body temperature, but towards the end of the second day the temperature began to fall rather rapidly, and continued low on the third day, after which it was not taken. Paralysis supervened on the fifth day, and became general, and death ensued on the six day. In the animal which received the antitoxin as well as the toxine there was no effect on the body temperature, which did not fall or rise. No symptoms were observed, and the animal was killed in forty-one days, being fat and well-nourished. In the animal that received the toxine alone the weight began to fall soon after the injection, and on the second and third days there was a rapid fall—nearly 250 grammes being lost during this time; and the weight continued to fall until death ensued, on the sixth day. In the animal, however, that received the antitoxin and toxine there was a slight rise in the weight, which continued until the animal was killed. To all appearances, therefore, the antitoxin in this experiment completely counteracted all the effects of the toxine or the diphtheritic ferment. The absence of any effect on temperature, the absence of paralysis and the gain in body weight show this. The post-mortem examination of the animal that died from the toxine showed well-marked fatty degeneration of the heart-muscles and characteristic nerve degeneration, one of the branches going to the vastus internus. In the antitoxin animal there was no fatty degeneration of the heart, but some of the branches of the nerves to the

Digitized by Google

vastus internus muscle showed the characteristic degeneration. The dose of antitoxin given to this animal, therefore, did not counteract all the effects of the toxine since some nerve degeneration was produced. The immunity strength of the specimen used (British Institute of Preventive Medicine) was great; and the amount injected was more than sufficient to counteract the effects of the toxine according to the calculations in vogue. A few other experiments were performed on the effect of the antitoxin in preventing the symptoms which have been described as produced by the injection of the diphtheritic albumoses into the blood. In one experiment two rabbits were chosen, and into each was injected on two occasions 7 centigrammes of albumose. In one animal 0·5 c.c. of antitoxin was injected with the albumose. After the first injection the temperature rose, then sank rapidly, recovering however the following morning. A second injection at this time produced high fever, succeeded by a fall on the same day, after which the temperature on the third and fourth days was practically normal. The animal that received albumose as well as antitoxin showed after the first dose no rise of temperature, but a well-marked fall, with recovery on the second day. A second dose now given showed a rise of temperature, succeeded by a fall, after which, on the third and fourth days, the temperature was normal. The body weight shows in both animals a gradual increase up to the eighteenth day and later, as in all healthy rabbits which are taken from the stock, placed in cages, and receive an abundance of food. The antitoxin in this case, therefore, although it diminished, did not prevent the effects on the temperature which normally result from the injection of albumoses into the venous system. In another experiment a much larger dose of albumose was given—namely, 0·125 grammes, on two successive days, followed by 0·072 grammes on the third day. In one animal antitoxin was given with the albumose, 1·4 c.c. being given altogether. The effect on the temperature when the albumose alone was given was a slight rise after the first dose, no rise after the second, but a well-marked rise after the third, lasting over the following day. In the antitoxin animal, following the first dose was a fall of temperature; following the second dose practically no effect; following the third dose a rise of temperature of the same character as that in the first animal, but rather less in degree. The effect on the body weight is well marked; the animal that received the albumose alone showed a nearly stationary weight for seventeen days, a slight increase being observable, but very slight. The animal that received the antitoxin as well as the albumose, however, showed after the first week a rapid rise of body weight, contrasting strongly with the first animal. The animal that received the albumose alone showed on the fourth day slight weakness in the hind legs; on the sixth day this was more pronounced and gradually increased till the seventeenth day, when it presented an appearance in marked contrast to the antitoxin animal. The latter was lively, and walked about the room like an ordinary rabbit; the former, when taken out of its cage, lay quite quiet, the legs half extended; it walked but little, and then with only feeble attempts. Both animals were killed on the twenty-third day. In the albumose animal there was well-marked fatty degeneration of the heart and degeneration of the nerves examined (phrenic and anterior crural), while in the animal that received antitoxin as well there was no fatty degeneration of the heart, and the degeneration of the nerves was insignificant in extent. These experiments are only the commencement of an inquiry into the subject, but they are in themselves quite definite, and tend to show that the antitoxic serum is capable of counteracting to a great extent the poisons which are found in the tissues of patients dead of diphtheria.

Discussion on Diphtheria.

The PRESIDENT, in calling for discussion upon the subject, announced that as the time at the disposal of the section was limited it would be better that those speaking should give what they had in crystallised form in their brains rather than long prepared papers.

Dr. GOODALL opened the discussion with an expression of the opinion that the most severe cases of diphtheria were those in which there was a persistence of the false membrane, rapid pulse continuing for a lengthened period, albuminuria, especially at the end of the first week, pyrexia, drowsiness, and vomiting, especially if frequent. Cases in which anuria was a feature were also hopeless, as were also those in which hæmorrhages into the skin, retro-peritoneal structures and heart muscle occurred. From Jan. 1st to June 30th he had under his care 241 cases of diphtheria in which the clinical and bacteriological diagnosis coincided. Of these, he had treated 105 with antitoxin and 136 without it with a difference of 11 per cent. in favour of those treated with antitoxin. At all ages this was the same, except over ten years, when the mortality seemed to be somewhat greater than when antitoxin was not used. Amongst his tracheotomy cases he had a recovery list of 64 per cent. As regards albuminuria he could not say that the use of antitoxin lessened the incidence of this disease, but certainly anuria was more frequent in those cases in which antitoxin was not used. As regards paralysis he found that it was met with far more frequently in severe than in mild cases; but, so far as his experience went, the cases were quite as frequent when antitoxin was used (17·1 per cent.) as when it was not (14·7 per cent), though here the difference might be because the number of recoveries was greater, as the paralysis was found to occur especially in the post-membranous stage of severe cases. He found that other forms of treatment were not of much value as adjuvants, but he was convinced that he was more successful in cases of pure diphtheria than when complicated with scarlet fever, whilst complicated with measles it was extremely fatal, as also with bronchitis and broncho-pneumonia. Taking it altogether, he was convinced that the antitoxin treatment was the best at the disposal of the medical man to save his patients, and as he wished to save his patients he should certainly continue to use it.

Dr. JOHNSTON considered that the following features characterised the more severe cases of diphtheria—albuminuria during an early stage of the disease, persistent patches of exudation, symptoms pointing to the probability of cardiac failure supervening, slight enlargement and pain of the cervical glands, and the general asthenic condition now so well recognised. Paralysis of the uvula, he thought, could scarcely be classed along with paralysis in other muscles as a sign of the severity of the disease; but he thought that a rapid pulse, becoming gradually slow and irregular, a diminution in the quantity of urine, accompanied by an increase in the amount of albumen therein, and vomiting were all exceedingly grave symptoms. As regards the diagnosis he was not yet thoroughly satisfied that bacteriological diagnosis was in all cases to be relied upon, and from his experience he had concluded that it was improbable that only one organism was the cause of the disease, although at the same time he admitted that the Klebs-Löffler bacillus might be present without any distinct sign of diphtheria. So far as he was concerned the results obtained by the use of antitoxic serum were somewhat disappointing. In Glasgow, at the Belvedere Hospital, they had a previous mortality over five years—highest 41·4 per cent., lowest 28·63 per cent. In Manchester his highest mortality had been 44 per cent. and his lowest 15 per cent. Since the commencement of the antitoxic serum treatment in Glasgow with material obtained from the British Institute of Preventive Medicine he had used it at first only in severe cases, and all of the cases died; but in 105 cases treated with antitoxin the mortality was 15·2 per cent. These were not the hopeless cases, but none of the mild ones were included as their stock of serum was small; the moribund and the mildest cases were not treated, and amongst these there was a mortality of 17·5 per cent.

Professor VON RANKE of Munich said that he wished to give the results of nine months' work in his diphtheria wards, during which period he had had 197 cases. Separating those complicated with scarlet fever and measles he had left 163 of pure diphtheria, and a death-rate amongst these—which were, he might say, severe and most grave cases, as only these were sent into hospital by medical men—of 17·7 per cent. Most of these cases were submitted to bacteriological examination, and in 93·8 per cent. Löffler's bacilli were found, in 12 cases in pure cultivation. As regards the cases in which croup was developed, of which 58·3 per cent. had croup on admission, he found that in 61 intubation was used, and amongst these there was a death-rate of only 32·7 per cent. In most cases the tube could be removed at the end of twenty-four hours, and in only three was it necessary for four days. In these cases he thought it advisable to perform tracheotomy. In every case he removed the tube each morning in order to determine whether it was safe to leave it out or not. Amongst his cases he had 68 in which the pharynx only was affected, with a mortality of 2·9 per cent., both cases being due to heart failure. He had 19 cases of septic

Digitized by Google

diphtheria, in only one of which death supervened. Of 2 cases in which the larynx was affected both died. It must be borne in mind that the septic and mixed diphtheria cases were not the same. Of those cases treated on the first day there was a mortality of 5·2 per cent., of those on the sixth day 40 per cent., and of those on the seventh day 46·6 per cent. As regards age, he had 5 cases under twelve months, all of which died; under two years the mortality was 37·5 per cent.; whilst of those over seven years of age only 7·7 per cent. died. Comparing this with the mortality in Munich for the previous eight years he found that the mortality had ranged from 42·2 per cent. in 1887 to 57 per cent. in 1894. So that in his clinic the fall was enormous. He considered, however, that the change of the clinical course of the disease offered even greater encouragement than statistics. He now found that the disease had lost its progressive course, and that cases of laryngeal stenosis should be intubated within the first twenty-four hours, and if not done then it was never found to be necessary, whereas under the old system he had often found it necessary to intubate or operate even four or five days after the patient was admitted.

[Our report of this debate will be continued next week.]

SURGERY.

Address of the President of the Section.

Sir WILLIAM MACCORMAC, Consulting Surgeon and Emeritus Lecturer on Clinical Surgery, St. Thomas's Hospital, delivered an address on Some Points of Interest in connexion with the Surgery of War. He said:—As the chief duty of a general is to bring his men into the fighting line as physically fit as possible, and to be as little hampered as may be by sick and wounded, it is hardly possible to over-estimate the value of a carefully prepared military medical organisation, or to lay too great stress on the responsibilities which devolve upon the medical officers in the field. The chief surgeon of the army should not only possess the willing support of his executive staff, but he should be, and generally is, the right hand man of the general commanding, enjoying his full confidence and active sympathy, else the disasters which have occurred before may occur again. This unfortunately is not his position in our army, for in spite of strenuous opposition from the Medical Department he is placed on the staff of the officer commanding the lines of communication, and not, as in most other armies, on the staff of the commander-in-chief. The modern rifle has introduced changes which have excited universal attention. This weapon sends a small hard projectile with enormously increased velocity to a much greater distance and with greater precision than was previously possible. Our troops used the Lee-Metford rifle in the recent Waziristan expedition and later in Chitral. The volleys were almost smokeless and noiseless, and wrought great havoc in the enemy's ranks. Examples of gunshot injuries from this source have not yet come to hand. Except cases of accident and suicide there are as yet but few specimens obtainable of the effects of the modern bullet on living persons; but we have a large experimental record from various countries of the effects produced both on the human cadaver and on animals. The experimental results are not exactly similar to those obtained in actual warfare, as the effect of a bullet striking a dead body is necessarily different to that it would have on a living person.

[Sir William MacCormac here detailed the dimension, weight, velocity, and range of modern rifle bullets. He continued:]

Vascular tissues, cavities like the skull filled with semi-fluid matter, and organs like the liver or spleen, are liable to suffer most from the so-called explosive influence. By this term is not meant the injury caused by the forbidden explosive bullet which the terrible appearance of the wound so strongly suggests, that in war time allegations are constantly made that these prohibited missiles are employed. The entrance wound may present nothing peculiar, but the soft parts within are pulpified, and the destruction of tissue extends for a considerable distance around the bullet track. The exit wound is large and lacerated, as if the soft parts had been burst outwards. When the bone is struck it is extensively comminuted, pulverised, and driven in all directions into the tissues. The wound beyond the bone is conical, the apex at the bone and the base at the surface. When an empty leaden box or tin, or an empty skull, is traversed by a bullet, the openings of entrance and exit will closely correspond to the size of the projectile; but if a closed or partially closed vessel of this kind be filled with wet sawdust, water, jelly, or damp clay, and a similar projectile is fired at it from the same distance, it bursts and the contents escape. William Busch was the first to suggest that these effects were the result of the sudden increase of hydraulic pressure in the parts struck. This explanation is not strictly accurate. The pressure is not truly hydraulic, as it is not exerted equally in all directions, but chiefly in the direction of the flight of the projectile, and it occurs in almost equal degree in both closed and entirely open leaden vessels filled with fluid or jelly. The cubic capacity of a closed vessel is in many instances increased nearly by a third, and in the open vessel the increase is one-fourth or one-fifth. The increase in volume is as much as 300 times the bulk of the projectile. The bullet also appears to have already traversed the vessel before this hydraulic influence has had time to take effect, for in many instances the displaced leaden tags at the exit wound can be restored to their original position, and the completely circular opening by which the bullet emerged reproduced. Water has, in fact, an astonishing power of resisting the progress of a bullet which, although capable of travelling perhaps 4000 yards through the air, will be arrested altogether after traversing three or four yards of water. Within the short time at my disposal it is impossible to discuss this difficult subject, but the explanation of the extraordinary development of explosive effect seems to depend on the rapid arrest of the flight of the bullet on piercing fluid matter, and its motion being transferred to the parts immediately surrounding it, and these again transmitting it to parts further removed, somewhat as wave circles are produced by a stone dropped into the smooth water of a pond. Bruns's experiments may be taken as a type of those made with reduced charges. He found intense explosive effects up to 400 yards. These attained their maximum in the skull, the bone being fractured in all directions, and upon semi-fluid organs, like the liver, spleen, a full stomach, or intestine, terrible damage was inflicted. In the elastic lung tissue, however, or upon empty viscera no effects of this kind followed. When the bone was implicated the track as far as the bone was usually no larger than the ball, but the tissues beyond were always extensively damaged and the exit wound was very large. At a distance of 400 to 800 yards explosive effects were only witnessed in the skull. Soft parts were traversed by a narrow channel no larger than the bullet itself, and with but little damage to surrounding tissues. The joint ends of the long bones presented keyhole openings, accompanied by much less extensive fissuring than was formerly the case. When the shaft was implicated the comminution was not extensive, the fragments were large, not detached from one another, and the exit wound small. At a range of 800 to 1200 yards explosive effects were only occasionally produced in the skull, and in a much diminished degree. In soft parts a narrow channel was made with little surrounding damage. In the spongy bones perforations occurred with but little fissuring, and in the compact tissue of the shaft there was comparatively little comminution. Finding that the experiments of Reger, Beck, and Bruns in Germany, and those of Delorme, Chavasse, Chauvel, and Nimier in France, and the conclusions derived from them materially differed, the Prussian Kriegs-Ministerium undertook a series of experiments, conducted so as to exclude sources of error as far as possible, and thus obtain for military surgeons trustworthy information as to the character of the injuries which the new weapon would produce in time of war. In the first place, full charges of powder were employed, and as the range varies from 25 to 2000 yards wounds of every description were obtained. These are represented by 1000 preparations preserved in the Friedrich Wilhelm Institute in Berlin, and the more important are given as full-size illustrations in an atlas of plates issued by the War Ministry. The bodies fired at were covered with shirting to estimate the frequency with which portions of clothing are carried in, and to give the tissues the normal amount of fluidity Wickersheimer's solution was injected, the tension of the bloodvessels being approximately maintained by injecting animal blood serum into the arteries immediately before the experiment. Up to 1200 yards single shots were discharged, and beyond this volley firing was resorted to. The bullets were collected in bags of sawdust, and in the case of each separate shot the bullet was examined in relation to the

Digitized by Google

wound it had produced; after volley firing this, of course, could not be done. The 900 experiments made by the German War Office do not justify Bruns's classification of gunshot injuries into groups according to range. As the range increases there is a gradual diminution in the velocity and energy of the projectile, and a corresponding diminution was observed in the extent of the injury. The bullet in nearly every case was found to go straight through the part struck, and the old-fashioned contour shot was never met with. The human body is traversed with ease at 2000 yards, and the skull, thorax, and abdomen will suffer alike. At less than half this distance the old bullet has lost most of its momentum, and becomes flattened out or impacted when it strikes a bone without penetrating deeply. In wounds of the abdomen the liver showed the largest amount of damage, and in some cases of suicide large portions of it were reduced to pulp. Up to 1200 yards the entrance wound was usually large and stellate; and the exit track funnel-shaped, with lateral rents extending from it. In the spleen and kidneys similar injuries were produced. In the intestine each bullet produced on an average three openings, and in some cases as many as eight, and the extent of the damage seemed to bear no defined relation to the length of range. It was more extensive when the intestine was full. Fearful destruction of skull is produced by a small 5 mm. (0·2 inch) bullet at 50 yards range. The vault is completely shattered, the base extensively split open, and the brain destroyed. The 8 mm. bullet produces similar results, but as a rule the fragments hold together. At 100 yards the entire vault is shattered, fissures extend from both entrance and exit wounds, and a gaping line of fracture was constantly found extending between them. The fissuring around the wounds of exit and entrance shows two different types, one circular the other radiating, and the base is also traversed by fissures. Up to 1600 yards the fissures gradually diminish or disappear, with the exception of the one connecting the entrance and exit wounds, and sometimes a clean perforation occurs, which becomes frequent at 2000 yards. Gunshot fractures of the long bones are very frequent and possess great interest. They vary according to which bone or part of the bone is struck. The effect upon the spongy extremities and upon the compact tissue is very different. From 100 to 200 yards the shaft of the femur is broken up into small pieces for an extent of from three to five inches, and the humerus from two to six inches. At the entrance wound in the bone the fragments remain in part attached to the soft parts, but at the wound of exit they are completely separated. The adjacent muscles are filled with bone *débris* and detached fragments of bone, the muscles and tendons are torn, and the exit wound in the soft parts is large and ragged. In the spongy bones and spongy extremities of the long bones the crushing and fissuring at short range are also great, but the fissures are often concealed by untorn periosteum, and there is less damage to the soft parts at the wound of exit. At a range of 600 yards there are occasionally keyhole shots with radiating fissures in the spongy tissue, and at 800 yards the keyhole channels become frequent, but even up to 1600 yards the compact tissue is extensively fractured. At 1200 yards the fragments of bone as a rule are no longer driven into the soft parts beyond; but this happens occasionally even up to 2000 yards.

The conclusion to be drawn from the German experiments is that the damage to the shaft of a long bone is very extensive for all ranges up to 2000 yards, the main difference being that at short ranges of 200 or 300 yards—for example, the fragments are more numerous, smaller, and more stripped of periosteum, while the converse obtains at longer ranges. The great velocity, comparatively small size, and hardness of the modern projectile render it much less liable to lodge in the body. It nearly always traverses the part struck and is seldom arrested in the tissues, thus avoiding a source of much after trouble and suffering. The disastrous searching for lodged bullets and repeated attempts to extract them, which formed so considerable a part of the older military surgery, will now be largely done away with. Most surgeons of experience have arrived at the conclusion that the wounded often incur greater risks from the protracted search made for the foreign body than any the bullet itself would cause if left alone, a remark which does not apply to the necessity for removing particles of clothing which may be carried in, which are, of course, septic. The new projectile does not contuse an artery or push it aside. There is no evidence that an artery is ever deflected and thus escapes injury, and, except at short range, the bullet never wholly divides one of considerable size. Cases where a large artery is wounded generally die before help arrives, and it is interesting to know that in the late war in China the Japanese surgeons had such perfect arrangements that in two cases—one a wound of the brachial, the other of the femoral artery—the vessels were tied and the patients saved in the fighting line itself.

Perhaps the most important matter to consider is how far the injuries inflicted by the new projectile will be more amenable to successful treatment. In a memorable paper communicated to the first Congress of German Surgeons Volkmann pointed out that the subcutaneous character of gunshot injuries of bones and joints made them less dangerous than compound fractures with more extensive damage to the soft structures produced by other causes. Subsequent experience has helped to confirm this view. Pirogoff has told us how astonished he was at the easy manner the wounds produced by the small Circassian copper bullet healed during the Russian war in the Caucasus. Not only flesh wounds, but often penetrating injuries of the chest and of the joints were readily recovered from with scarcely any suppuration. During the recent war in Chili it is reported by Dr. Stitt that flesh wounds which had not been probed and thus infected readily healed under a scab, that the favourable character of lung wounds was especially noticeable. The bones were less comminuted, and united in about half the time formerly required. Dr. Rivero of Valparaiso has made similar observations. He noticed especially the smallness of the apertures caused by the Mannlicher rifle bullet, and that the injuries generally were less dangerous to life. I have received a very favourable account of the character of the wounds caused by the Lee-Metford bullet from Surgeon-Lieutenant H. Burden, who was present at three actions during the Chitral expedition. He reports that, so far as he has seen or heard from others, the wounds through the soft tissues at both short and long ranges were clean and incised, with very little or no bruising, and that they quickly healed. Through the bones clean punched-out holes were made with little splintering, and he said in no case was there any explosive action. The damage caused by the large bore bullets of the enemy was much more severe. Another interesting report from Chitral has been received in a private letter from Surgeon-Lieutenant C. H. Evans, I.M.S. The seriously wounded and dead, he writes, were all carried off the field, but later on many of the Swatis, with uncomplicated wounds of the soft parts, came in to be dressed and were treated by Surgeon-Lieutenant Evans, who reports that these cases healed rapidly and well, notwithstanding the use of dressings very far from aseptic applied by the men themselves. In reply to questions, these patients informed Surgeon-Lieutenant Evans that the reason why none of the more serious cases had come for treatment was that "all the men who had suffered fracture of long bones were dead"; these people knew what they were talking about, because the cases referred to were those of their own relatives and comrades. During the French war I have often seen Chassepot bullet wounds heal without suppuration. Longmore never saw a gunshot wound heal in this way, and indeed considered suppuration to be inevitable. In the Russo-Turkish war von Bergmann treated severe gunshot injuries of the knee not only with success as regards preservation of the limb, but also in respect of restoration of function, and this even when the bones were extensively implicated. Of fifteen cases only one died. In eight there was no suppuration, although in three of these the projectile had lodged. Reyher had twenty-eight similar cases without a death. Two instances are reported by the Prussian Surgeon-General of gunshot through the knee at a distance of only 100 yards treated by occlusion which recovered with a movable joint. When the new projectile traverses the lung the track is uniformly cylindrical, smaller than the bullet, and smooth-walled, with little contusion of the surrounding tissue, and splinters from injured ribs are but seldom driven in. Severe damage was only found where the bullet had struck transversely, had carried in fragments of rib, or wounded a large vessel or bronchus. In many cases no serious symptoms were produced, and a diagnosis was only arrived at by the position of the wounds of entrance and exit. In others there was cutaneous emphysema, hæmoptysis, difficult respiration, and pneumo- or hæmo-thorax. Death in every instance was due to injury to the great vessels or bronchi at the root of the lung, and, excluding cases of suicide, the mortality in the cases recorded was only 12·5 per cent. The wounds healed in most cases without trouble in three

Digitized by Google

weeks' time on an average. Only once did empyema occur showing the generally aseptic nature of the wound, and the subcutaneous character of the small openings produced by the bullet. The treatment, therefore, will be mainly directed to sealing the wounds of entrance and exit, and operative interference will be rarely required except for serious hæmorrhage. Unfortunately, gunshot wounds involving the brain and the abdominal cavity remain as fatal as before. In the war of 1870–71 about 10 per cent. of the total number of gunshot wounds were of the head, but only about half of these were perforating. In future wars every bullet which touches the skull, even up to 2000 yards and more, will probably fracture it extensively, and at 3000 yards the bullet may perforate and lodge. These cases, almost without exception, die either immediately from the injury to brain tissue and shock or by hæmorrhage and subsequent inflammation. Very few indeed suggest operative interference or any hope of a favourable issue, but to these the ordinary rules of practice would apply. In 1870–71 a large proportion of the wounds of the abdomen did not perforate the cavity, but in future this will not be the case, as even at the longest ranges the new projectile will traverse the abdomen and wound its contents. No probing should be attempted, and Senn's inflation method is likely to do harm by forcing fæces through the wounds in the intestine into the abdominal cavity. Hitherto cases of this kind have ended fatally, and in the next war it is to be anticipated that the mortality will also be very great. As a rule those injured in this way do not die immediately unless a trunk vessel be divided, but will be carried to the dressing stations and shortly succumb to hæmorrhage or infective peritonitis, the result of fæcal extravasation, or of matter carried in by the bullet. Nothing is of avail in these cases but very early laparotomy, for when peritonitis has set in operation will come too late. It has been suggested that the field hospitals should possess an outfit for the operative treatment of gunshot injuries of the abdomen, and that wounds of the viscera should be dealt with by suture, aseptic tamponade, or, in some instances, by partial or complete removal of the injured organ. But I fear that anyone who has seen the trouble and confusion of battle, the sudden and overwhelming amount of work and strain thrown upon everyone concerned, and the impossibility of adequately meeting the great emergency will regard proposals such as these as scarcely practicable. I think we are justified in believing, although there is high authority for a contrary opinion, that the next great war will be more destructive to human life than any of its predecessors. But very many cases will remain less severe in character, more capable of successful treatment, and less likely to entail future disablement, while improved sanitation and antiseptic methods will enormously increase the proportion of recoveries. It is the unceasing effort of modern surgery to provide antiseptic protection in an effective form in time of war; and I may be permitted to recall that the medical organisation during our last war in Egypt was so complete in this respect that not a single case of infective wound disease occurred during the whole campaign.

Rhinoplasty in India.

At the opening of this Section Brigade-Surgeon-Lieutenant-Colonel KEEGAN read a paper on Rhinoplasty in India. He commenced by remarking that in England rhinoplasty was required chiefly for cases in which the nose had been destroyed by lupus or syphilis; but in India the loss of tissue was most frequently the result of injury. The chief points in the operation were as follows: A flap was raised from above down, composed of the tissues over the nasal bones; this flap was turned downwards so that the skin lined the future nasal cavity. A second flap was turned down from the forehead to cover the nasal bones and the first flap. The paper was illustrated by a lantern demonstration of photographs of patients before and after rhinoplasty. The results shown were very excellent.

The Diagnosis and Treatment of Fractures of the Upper Third of the Femur.

Sir WILLIAM STOKES opened a discussion on the Diagnosis and Treatment of Fractures of the Upper Third of the Femur by a paper illustrated by lantern demonstrations. He said that the difficulties met with in connexion with fractures in the upper third of the femur were very great, and many variations occurred in the signs present; there was usually shortening, but in some cases no alteration in length of the limb could be found, and occasionally it was said that there might be even slight lengthening; eversion was generally present, but sometimes inversion. Again, the shortening may occur immediately after the injury, or it may gradually develop. In some there is exuberant formation of bone, in others no attempt at development of new bone seems to be made. It was usually said that fractures of the cervix femoris did not occur in the young, but a photograph was shown of a specimen of fracture of the neck of the femur with the trochanteric epiphysis still ununited. A further element of difficulty was to be found in the fact that the more severe fracture was often due to the slighter injury. There are several anatomical details of importance in connexion with these fractures; the chief one is the presence on the neck of the femur of a fibrosynovial envelope, the so-called "cervical ligament" or retinacula, and on the integrity of this the final result chiefly depends. The cervical ligament is most marked anteriorly, where strong fibrous bands are present. When the cervical ligament is torn the blood-supply of the point of fracture is materially interfered with and non-union is exceedingly likely to result. After injury to the hip complete interstitial absorption of the cervix femoris often occurs, and this may result with or without fracture. Senile atrophy predisposes to this absorption. When the absorption occurs without fracture it is to be ascribed to a chronic osteoporosis set up by the contusion. The senile change referred to is not accompanied by any alteration in the angle formed by the neck of the femur; it was shown long ago by Sir George Humphry that though in the child the angle of the neck of the femur is greater than in the adult, yet when once adult life is reached no further change in the angle occurs. Certainly in some cases a diminished angle is found, yet these are probably cases of absorption resulting from contusion. The alteration in the angle of the jaw is in no way parallel resulting as it does from muscular action, not counteracted by the teeth meeting those in the upper jaw. The fractures under consideration may be divided first of all into those of the cervix of the femur and those of the base of the cervix. The fractures of the cervix are those formerly called intracapsular, and may be divided into those with penetration of the head by the cervix and those in which this does not occur, and further division of these groups according to degree of penetration and extent of laceration of the cervical ligament results in the formation of five classes of fracture of the cervix femoris. Of fractures of the base of the neck of the femur two main classes exist—those in which impaction occurs and those in which there is no impaction. The lesser divisions depend on the degree of impaction and its position. In one of these with partial impaction above there is great increase in the obtuseness of the angle formed by the neck, and this is the condition in which lengthening may occur. The eversion which accompanies a fracture of the cervix or of its base is the result of rotation of the shaft on the neck. The inversion which is occasionally present was attributed by R. W. Smith to the altered action of the adductors, which have become internal rotators owing to the forward position of the lower fragment but this explanation is unsatisfactory, and the inversion is probably caused by the limb having been in a position of inversion at the time the accident occurred. The differential diagnosis is from luxation, fracture of the brim or fundus of the acetabulum and from contusion. The chief points in the diagnosis were then given. As to treatment there was some difference of opinion; fixation had been condemned as the fragments were said to be drawn asunder; the danger of keeping aged patients for a long time in bed had also to be considered. Senn in 1883 made a large number of experiments on cats and dogs, and he found that after fracture of the neck of the femur simple fixation by plaster-of-Paris in no case resulted in bony union, but that pegging with bone or metal nails always gave rise to union by bone; he advised lateral pressure on the great trochanter, and he considered it important not to break down an impaction. Southam recently broke down an impacted fracture of the base of the cervix of the femur in a patient aged twenty-seven and put it up with extension; the result was perfect; but probably this treatment is only applicable in those rare cases where these fractures occur in young patients. It was important to bear in mind that in four out of the five classes of fracture of the cervix bony union can occur—that is to say, if penetration be present or the cervical ligament be intact. Rest, fixation, and some extension are the three important points in treatment. The extension must on no account be too great. He had not employed lateral pressure, and it did not seem to be necessary. Bryant's splint was a suitable one for most cases, but the

Digitized by Google

modification introduced by himself was of much value for old people, as it allowed the patient to sit up in bed. Lastly, one should remember that the farther the fracture was from the base of the neck the less chance there was of boney union.

Sir GEORGE HUMPHRY considered the treatment the most important part of the subject. Fractures in any part of the body will unite at any time of life if the parts are only kept in contact. The angle formed by the neck certainly does not alter in old age, but thinning of the cancelli does occur, and this is probably due to the devouring tendencies of the cells with which the cancelli are surrounded. The cancelli are necessary to enable the upper part of the femur to withstand the shocks to which it is subjected; and from this fact resulted the rarity of fracture in this situation in the young and its frequency in the old; yet the bone-forming power of the cells thrown out is not lost, and so bony union is common. At the base of the neck of the femur bony union is the rule, and it is rare to find specimens of fractures in this situation showing non-union; often much bony material is thrown out, and firm bony union may result even after great comminution. Fractures inside the joint occur, as might be expected, where the bone is narrowest—that is, close to the head. In this case bony union is liable to fail. This is not due to any want of bone-forming power on the part of the patient, for a fracture elsewhere unites readily; it is not due to any lack of blood-supply, as every part of a bone is adequately supplied with blood. There are two causes to which the non-union may be attributed: (1) the fact that there can be no overlapping, as the head is embraced by the acetabulum, and there is generally a diminution of the amount of bony surfaces in contact; and (2) the new bone-forming cells which are exuded at the seat of fracture are not detained there, but escape into the joints. He showed a drawing of a femur in which a fracture of the neck had occurred a year before death; the patient was eighty years old, and bony union had occurred. The retinacula (the fibrosynovial ligament) are stronger in front than elsewhere, but it is also more adherent there; hence it is much more commonly torn in front. The absorption of the neck, which so often follows fracture, may take place very rapidly, and this chiefly, if not exclusively, takes place between the fracture and the great trochanter (a specimen illustrating this was exhibited); the absorption is due to the rubbing of the trochanteric part on the inner fragment.

Mr. BRYANT said that he thought the classification of fractures about the neck of the femur into eleven divisions, however useful from a pathological or museum point of view, was of but little value clinically. The distinction between intra-capsular and extra-capsular fractures was not of much importance for treatment. The presence or absence of impaction was probably the chief point to determine. He thought that most fractures of the upper end of the femur were impacted, and that it was of great importance to try to keep them impacted. He agreed that the inversion occasionally met with was due to the position at the time of the fracture; in these cases the anterior part of the neck is driven into the trochanter. As to treatment, immobility, quiet, and not much extension are the essentials. In forty-two consecutive cases of his of fracture of the neck and base of the neck of the femur, with an average age of seventy, all went out with good and useful limbs. One great danger is to attempt to make the diagnosis very certain by excessive manipulation of the part in a useless wish to obtain crepitus. As to impacted fractures, undoubtedly the general rule should be not to loosen the impaction, but exceptions do occur. He mentioned that he had a case now under treatment, a lady of thirty years old, who had an impacted fracture of the upper end of the femur and inversion of the foot; he loosened the impaction under an anæsthetic by rotating outwards, and put it up in a double splint. Now, three weeks later, there is no shortening, and much callus has formed at the base of the neck of the femur.

Professor BENNETT (Dublin) preferred to classify these fractures according as to whether they were produced by direct or indirect force. Of 136 specimens of these injuries, forty-six were intra-capsular and seventy-two were extra-capsular—figures very different from those given by Malgaigne. In attempting to cause dorsal dislocation of the head of the femur in two cases an intra-capsular fracture had resulted; the bodies were of persons between seventy and eighty. In all the impacted intra-capsular fractures (six in number) bony union had occurred. Rest and contact of the fragments will ensure osseous union. All the extra-capsular fractures were impacted, and were due to violence applied over the great trochanter, or to falls on the feet or knees.

Mr. GREIG SMITH (Bristol) said that pathological classifications did not form good clinical foundations. The best classification is into those due to indirect violence and those caused by blows over the great trochanter. The former variety of injury gives rise to a fracture of the neck anywhere, but usually near the head; the latter causes fracture of the neck anywhere, but especially near the trochanter. He considered that the obliquity of the fracture was important, and that in an indirect fracture more of the posterior than of the anterior surface is chipped off. The want of union in fractures due to indirect violence is caused by the absence of a nidus for the development of the new bone.

Mr. MAYO ROBSON said that elaborate classifications could only be taken from the post-mortem rooms, and were useless clinically. The best classification was into impacted and non-impacted. As to treatment, apposition is of chief importance, and the fracture should be disturbed as little as possible. In the case of old people, they should be put to bed, and treated with a long splint, with weight and pulley; if recumbency be well borne the treatment may be continued, but if badly borne a Thomas's hip splint and a starched bandage should be put on, and the patient allowed to get about. As to impacted fractures in young people, he thought that Mr. Southam's case could hardly be the first in which the impaction had been loosened intentionally.

Professor SINCLAIR (Belfast) said that bony union occurred much more frequently than people thought. The chief point of value is the history of the injury. When an intra-capsular fracture is due to an external rotary movement the periosteum is not so likely to be torn, and bony union is likely to occur. Many of the specimens he had examined had had no treatment, and yet osseous union had taken place. He did not consider that any splint was needed for impacted cases.

Sir WILLIAM HINGSTON (Montreal) said that the results obtained in this country seemed much better than those they could obtain on the other side of the Atlantic, as there non-union in fractures of the neck was the rule, and that it was very rare to get union without any shortening.

Mr. T. J. GANT thought shortening was always present.

Dr. S. H. WEEKS (Portland, Maine, U.S.A.) considered the diagnosis of great importance, and in this direction the pain, worse on movement, was of great value. The age of the patient and the history of the injury must also be taken into consideration.

Mr. C. B. KEETLEY said he thought that fractures of the upper third of the femur should be treated like any other fracture. In one case under his care he operated on a woman who had had fracture of the neck of the femur a year previously, and removed the head, which had become ankylosed to the ilium; the result was favourable. For some very oblique fractures of the femur with much shortening he advocated the use of the pins which he had devised.

Sir WILLIAM STOKES, in reply, said that he thought the tearing of the cervical ligament greatly interfered with the blood supply of the upper fragment, and was the chief cause of the want of bony union. The classification he had put forward seemed to him to be of value as influencing prognosis.

Movable Kidney.

Dr. KENDAL FRANKS gave a lantern demonstration on Movable Kidney, and explained the retention of the kidney in its normal position as the result of the pressure of the neighbouring viscera. This was well shown from specimens of kidneys hardened in the body by means of injections of Muller's fluid; these kidneys displayed well-marked depressions caused by the liver, bowel, and other organs. The symptoms (gastric crises) accompanying movable kidney could be easily explained by the mechanical effects of traction on the duodenum or colon.

OBSTETRIC MEDICINE AND GYNÆCOLOGY.

Address by the President of the Section.

Sir WILLIAM PRIESTLEY, Consulting Physician to King's College Hospital, late Professor of Midwifery in King's College, took for the principal subject of his address Over-operating in Gynæcology. He said:—

In opening the Section of Obstetric Medicine and

Digitized by Google

Gynæcology it may be appropriate that I should say a few words as to the present position of this important department of medical science and art. Thanks to many workers, the progress has been so great as almost to merit the appellation of the word "marvellous," and I know no instance within recent days where the triumph of preventive medicine has been so signally marked as in the application of the antiseptic system to midwifery. Puerperal fever has been practically annihilated in lying-in hospitals. Before the introduction of antiseptics, according to the figures of Le Fort, the deaths were then more than 34 per 1000; they have been reduced since the careful employment of antiseptics to fewer than 5 per 1000. Progress of a like kind has, however, not taken place in private practice. The researches of Dr. Boxall have made it clear that there is a large preventable mortality among puerperal patients attended at their own homes, and if this continues women delivered in lying-in hospitals may be actually safer than those confined in their own homes. In view of this state of things it has been determined to have a discussion in this Section on the precautions to be observed in private midwifery practice, and I am sure you will agree with me that its initiation could not be placed in better hands than Dr. Herman's. We can with great satisfaction look upon other advances in our art. One of the most notable is the improvement in the structure of forceps, more particularly the axis-traction forceps of M. Tarnier. The invention of this instrument marked a new era in obstetric practice. It affords greater security to the mother and child, and lessens the necessity for operations which imperil maternal or infantile lives—perhaps both. Modifications of instruments used for craniotomy and other like operations have made them, when actually necessary, easier in performance and safer for the mother, while the general adoption of antiseptics has greatly widened the field for such proceedings as Cæsarian section, Porro's operation, and symphysiotomy in cases of extreme deformity. But it is in the department of so-called gynæcology that in later days the greatest activity is to be noted. I can recollect a time when tapping was regarded as the only legitimate operation for ovarian tumours, and as this was only palliative and available exclusively for cysts containing fluid, the life of the woman, after the disease was established, was computed as worth at most but a five years' purchase from an actuarial point of view. In those days a great surgeon expressed the opinion that he who attempted the entire removal of an ovarian tumour ought to be indicted for manslaughter. Now, thanks to the introduction of anæsthetics and the careful observance of aseptic or antiseptic precautions, ovariotomy is not only sanctioned by the most conservative of minds, but it has had a success in many hands which evokes unqualified admiration. Enthusiasm may, however, readily be carried too far. I have witnessed the wax and wane of many enthusiasms which have had their day, and have had a share in bringing something like discredit on a department of practice which, rightly exercised, is productive of great good, but exercised unwisely is capable of producing infinite harm. Looking back on forty years of gynæcological practice I can recollect what has been termed a craze for inflammation and ulceration of the os and cervix uteri. During its prevalence it was said of some devotees that every woman of a household was apt to be regarded as suffering from these affections, and locally treated accordingly. Shortly afterwards came a brief and not very creditable period when "clitoridectomy" was strongly advocated as a remedy for numerous ills. This, fortunately, had a very limited currency, and was speedily abandoned. Then followed a time in which displacement of the uterus held the field, and every back-ache, every pelvic discomfort, every general neurosis was attributed to mechanical causes, and must needs be treated by uterine pessaries. Again, we had an epoch when oöphorectomy or castration of women was not only recommended and largely practised as a means of restraining hæmorrhage in bleeding fibroids, but also as a remedy for certain forms of neurosis even when the ovaries were healthy or not seriously diseased. Ere long it was discovered that removing the ovaries for neuroses, even if safely accomplished so far as life was concerned, besides unsexing the woman, was frequently followed by more severe nervous penalties than those for which it had been used as a remedy; that, in fact, it often entailed a loss of mental equilibrium, and sometimes ended in insanity. Close upon this, again, came an ardour for stitching up rents in the cervix uteri following childbirth—rents which were described as producing many hitherto unknown evils, and frequently conducing to the establishment of malignant disease. One votary of this practice boasted of having detected and operated on in a short period no fewer than 300 or 400 cases which he had found in examining 900 women. Surely here was a marked illustration of the *nimia diligentia*. No such experience, so far as I know, has been chronicled by any other writer. Lastly, we have had what has been described as an epidemic of operations for excision of the uterine appendages; and even now, although this operation has but recently come into vogue, I see there is a reaction against its too frequent performance and a demand in its place for more conservative methods which shall leave these parts of the generative system a chance of still performing their important functions.

[Sir William Priestley here urged that the anxiety of a patient to have an operation performed should not be allowed to outweigh the counsels of prudence against it, and he strongly condemned the employment of serious measures for the treatment of uterine fibroids unattended by active symptoms. He continued:]

One of the untoward results of spurious attempts at progress is that the announcement of some new proceeding or operation issued before its value is proved is apt to be taken up as the last new thing in science by many imitators, who, unwilling to be left behind, at once adopt it and use it perhaps in most inappropriate cases. Thus I have known the uterine appendages removed for matting together of parts by pelvic cellulitis and peritonitis after delivery because the patient was too impatient to wait for the slow recovery which would have taken place in due course. In like manner I have heard of the ovaries being removed for chronic metrorrhagia after abortion. Curetting, useful though it be in suitable cases, because it is new in fashion, has been proposed to cure a somewhat copious loss of blood due to the approach of the climacteric, which after a time disappeared spontaneously. The same treatment has within my experience been recommended for sterility in a young wife recently married, and who had no symptoms beyond her impatience to have children. Something operative must be done, and in lack of indication for anything else this was proposed in all good faith.

And now in conclusion I desire to say a few words on a subject concerning which I may not be in unison with many of the members of the Section, probably not even with some of its officers, but I am sure they will forgive me when I take the entire responsibility upon myself. The subject I allude to is the tendency in the present day of the obstetric physician to invade the domain of the surgeon in reference to what may be called external operations. In this country at least the departure is comparatively a new one. It may be that I have been brought up in a different and more exclusive school, and that the advance of age makes me unwilling to extend the boundaries of the work formerly allotted to the physician-accoucheur in hospital and private practice; but I must confess I have my doubts whether we are right in throwing aside the old restriction, and whether we shall enhance our position in the profession by doing so. I take it as quite certain that the College of Physicians, which has gradually been putting aside its prejudices and electing some physicians practising midwifery to its highest offices, is likely—covertly at first, and later perhaps more openly—to look askance at the claims for the Fellowship of those of its members whose chief work is avowedly surgical. The obvious suggestion to such members will be, Why not seek the Fellowship of the Royal College of Surgeons? And so a divorce may be gradually brought about between midwifery and the Royal College of Physicians. Whether it is judicious for the obstetric physician to extend his work into the domain of external surgery time alone can show. It is true the introduction of antiseptics has done much to minimise the dangers occurring in former days, but still the question we shall have to answer—and answer explicitly—is, Are our antiseptic methods a sufficient safeguard against the possible contamination of lying-in patients by one who undertakes extensive surgical work in addition to obstetric practice? I have been reading a recent contribution on ovariotomy by a careful surgeon, Mr. Malcolm, and I learn from him that notwithstanding all aseptic or antiseptic precautions, one of the chief dangers to the patient is still septic infection, and it was this chiefly which carried off his fatal cases. If this be so, careful as he may be, the medical attendant who goes to a midwifery case, after operating on an inflamed or suppurating ovarian tumour, or its subsequent dressing, or after removing a pyosalpinx, with its some-

Digitized by Google

times fœtid and infective contents, incurs a grave responsibility. Puerperal patients are much more susceptible of septic infection than the ordinary run of surgical patients. For the accoucheur deliberately to undertake a large amount of surgical work, with all its complications, is surely still further to add to his responsibilities, and perhaps imperil the safety of his obstetric patients. With careful antiseptic precautions there may be a relative safety; but who can say there is absolute safety, more particularly if a busy man has to go hurriedly to a midwifery case after operating on tumours inflamed and suppurating, or after dressing wounds in an unhealthy condition? I sometimes wonder what can be the reason why obstetric physicians wish to become surgeons. The field of work in obstetric medicine is equally interesting, and a mere facility in operating brings no abiding reputation unless conjoined with prudence and with the pursuit of science, which is as open to the physician as to the surgeon. Without this conjunction surgery becomes a mere handicraft. No one would pretend that the work done by Sir James Paget in the operating theatre was likely to enhance his reputation as much as his researches in pathology, or that the operative work of Sir Joseph Lister distinguished him in anything like the amount that his discoveries in antiseptics have done. The truth is that a mere skilful pair of hands, unless dominated by intellectual capacity and a high sense of responsibility, may become potential of more harm than good. But it may be asked what solution can be offered for the difficulty suggested. The answer would be, by appointing a gynæcological surgeon in every general hospital, who shall work in conjunction with the obstetric physician; and in all special hospitals for women have some physicians who do not operate, and who would advise with the surgeons. There is no lack of competent gynæcological surgeons now in this country, and in Paris, which I visited recently, I found a line of demarcation between obstetric medicine and operative gynæcology tacitly assumed. Each man, therefore, should take his choice, but not wish to be both physician and surgeon. I again ask you to pardon me if I have broached a subject in which I may not be in accord with many present. Some may think my views antiquated, but they must admit that they are at least in consonance with tradition, and I venture to think they deserve some consideration, since they are not out of harmony with our present knowledge and the advances of modern science.

The Aseptic and Antiseptic Precautions to be observed in Private Midwifery Practice.

A discussion upon this subject was introduced by Dr. HERMAN, Obstetric Physician to the London Hospital. In his speech Dr. Herman submitted three questions for consideration: 1. What is puerperal fever? This is a fever, he said, caused by the inoculation of septic organisms, which are not the same as saprophytes, but are descended from those which usually are associated with putrefactive changes. Those micro-organisms require a special soil for their development, and the generative passages during and subsequent to delivery offer a suitable field for their growth. Complete sterilisation or the destruction of all micro-organisms is what ought to be aimed at, but it is not practicable in midwifery practice. The second question is therefore naturally put: 2. How can puerperal fever be prevented? We have seen that sterilisation cannot be effected, and try to keep septic germs from the patient. This is to be achieved by asepsis or perfect cleanliness, and by antisepsis or the employment of germicides, and the one that is considered to be the most efficient by the opener of the discussion is corrosive sublimate, it being most portable and, upon the whole, the most trustworthy. The external antiseptic precautions consist of the purification of the attendants' hands by washing with soap and water, the use of the nail-brush, and soaking in an antiseptic solution, the boiling of all instruments used, scrupulous cleanliness in the dress of nurse and medical attendant, and the use of clean absorbent material such as antiseptic cotton-wool instead of napkins and sponges. The internal precautions are the restriction of vaginal examinations to the fewest possible, the washing of the genitals, the use of an antiseptic lubricant and vaginal antiseptic douches during and after delivery and throughout the puerperium. The use of the vaginal douche may do harm, and experience has shown that women whose labours are normal do as well without vaginal douches as with them; but in abnormal cases, as in lacerations or in cases in which intra-uterine investigation is required, not only vaginal but intra-uterine douches are necessary. The third question was, What are the differences regarding the prevention of puerperal fever between hospital and private practice? In answering this Dr. Herman said that in private practice there is less danger, and that antiseptic vaginal douches before delivery and during the puerperium may be dispensed with except in cases in which the discharges are unhealthy or in which extensive lacerations exist. As a general rule the antiseptic douche immediately after labour was advocated and should be given by the medical attendant. In private the nurse, it was averred, received less guidance, for the rules of a hospital are not always before her. To make up for this some obstetric physicians give their nurses a printed paper of directions to be followed during attendance on a given case, and this practice Dr. Herman recommended for general adoption. It was also stated that in private cases the nurse is under less discipline, but in all cases the medical attendant ought to insist on the complete obedience of the nurse to his directions.

Dr. STUART (Brooklyn) endorsed Dr. Herman's methods of aseptic and antiseptic procedure, and asserted that the essentials of antiseptics ought to be known both by medical attendant and nurse.

Professor LUSK (New York) advocates, in order to have as complete asepsis as possible, removal of all the hair from the external genitals. In regard to the employment of the douche afterwards, he considered that it was not only unnecessary but extremely harmful, as it washed away the natural secretions which prevent the germ from developing.

Dr. SMYLY (Dublin) asserted that it is not always necessary to make a vaginal examination, but by external palpation the diagnosis of presentation could be made out, and one of the first considerations was: what are the indications for a vaginal examination, as it is a procedure not free from risk?

The discussion was continued by Dr. SWAYNE, Professors PLAYFAIR (London), BYERS (Belfast), MURDOCH CAMERON (Glasgow), and Dr. MORE MADDEN (Dublin).

Electro-therapy as a Means of Diagnosis in Gynæcology.

A paper on this subject was submitted by Dr. G. APOSTOLI of Paris. It was shown that the faradaic current applied to the uterine cavity relieves ovarian pain of neurotic origin, but it is of little use in ovarian pain, the result of inflammatory lesion of the peri-uterine tissue or of the appendages, and is therefore useful in the differential diagnosis of pain. The constant galvanic current may be used in like manner and in inflammatory conditions of the appendages curable without radical operation the patient will bear the application better and better with a corresponding improvement of the prominent symptoms.

Dr. MORE MADDEN (Dublin) read a paper on Gonorrhœal Infection in some of its Gynæcological Aspects.

Dr. JAMES MURPHY (Sunderland) read a paper on the Surgical Treatment of so-called Puerperal Fever, which created a lively discussion.

PUBLIC MEDICINE.

The business of this section commenced on Wednesday morning by the delivery of an address on Public Health Legislation and the Needs of India.

Address by the President of the Section.

[Mr. ERNEST HART in his opening remarks reminded his hearers that what they said and did at this meeting would, according to its intrinsic merit, be likely permanently to affect public opinion and ultimately the municipal and legislative proceedings of the empire. He expressed the opinion that the metropolis of the world was the most healthy of cities, and he was proud to say that the science, art, and practice of public health administration "is almost wholly British; the other nations of the world have ..... accepted our demonstrations and followed our practice, but for the most part all of them still lag in the rear of British sanitary legislation and administrative practice." After referring to the Public Health Act of 1875, which brought into play principles laid down by Ramsey of Cheltenham, to whom was due the first great conception of the existing scheme of sanitary law, the speaker drew attention to some mistakes in the administration of the Public Health Bill, to which the names of Mr. Stansfeld, Mr. Sclater-Booth, and Mr. Dodson were attached, and pointed out that Mr. Ritchie's County Councils Bill, although it had done something to repair the mistakes of Mr. Stansfeld, had omitted to appoint medical officers to

Digitized by Google

make the work of the county councils effective. He continued:]

The few words which I have the duty to address to you as utterances from this chair must necessarily be limited to one or two selected subjects from the wide range over which our programme will extend. You will not be surprised if I deal especially with the subject which has so largely occupied my attention for the last thirty years—that of the relation of preventable disease to our water supplies—and if, coming as I do fresh from a study of the health conditions of India, I lay some stress upon the sanitary needs of that great empire, and some of the means of dealing with the most pressing of those requirements. It is now exactly thirty years since I succeeded in demonstrating, to the satisfaction of all authorised sanitarians, that the cause of the great epidemic of cholera of 1866 in the East-end of London was the temporary breaking down of a single pump in the works of the East London Water Company and the temporary disuse of one filter bed. This led to the distribution throughout the East-end of London of water from the River Lee, which had been for a few days polluted by the discharge from the sewers of the house of a family suffering from relaxing cholera, brought from Egypt to this country. That one strange concurrence of pollution and inadequate filtering, produced within a few weeks and within a limited area 16,000 cases of cholera and 6000 deaths.

I ventured to predict during 1892 that however often cholera should be landed in this country it could never become epidemic owing to the improvements in our water-supply, but that it must be limited to sporadic outbreaks in towns, ports, and rural districts into which it might be imported and where the water-supply is impure or inadequately protected. I by no means claim the exclusive credit of having preached and proved the doctrine that cholera is a purely water-borne disease, due to the tainting of our water-supplies with sewage; that doctrine was first laid down by Snow, of whom I was the convinced apostle. It was illustrated by Simon with all his wealth of quaint eloquence, but even until a late date it was doubted and denied by some of the most eminent authorities, and the official utterances of the Royal College of Physicians at no distant date were to the effect that it was not probable that in the case of cholera the influence of water will ever be shown to consist in its serving as a vehicle for the poison generated in the bodies of those who had suffered from the disease. The theory that cholera is wholly, essentially, and universally a water-borne disease is now becoming commonplace in Europe at least, although it is still ignorantly resisted in India, to the great peril and sacrifice of hundreds of thousands of lives of our fellow subjects. But even in England our water-supplies are still in too many places scandalously and dangerously tainted, and the result is shown in that prevalence of typhoid fever which is, as I contend, not less surely and inevitably traceable to a polluted water-supply than is cholera itself. Indian sanitation is not a scientific but an official system. There does not exist there any independent medical opinion. The oldest men in the service are the highest in official position. Their ignorance is the standard by which their juniors are bound, their prejudices become a despotism and their follies a tyranny. It was for a long series of years as much as a man's promotion was worth to dare to avow the opinion that cholera was a water-borne disease, and that it was carried from place to place along the lines of human communication. The idea that it was spread and diffused by great concourses of people becoming infected by the sewage-tainted water of religious festivals was treated as not only a folly, but an offence. The two things may be concurrent, said an eminent official, but it is a wild absurdity to treat them as cause and effect. This gentleman still holds high office at an advanced age, and it was he who was sent from the India Office to represent this country at the recent Conference on Cholera in Paris

[The speaker then referred to the army medical regulations for the management of cholera, which he characterised as a discreditable and dangerous document, and spoke of the discouragement of sanitary studies by the Government of India and the overloading of inconsistent duties. In conclusion he said:]

Two things struck me in India—the remarkable ability, the enormous power of work, and the excessive overwork of the Indian medical officers, the terrible servitude which enforces on them the attempt to perform a vast mass of duties which cannot be performed, and the lamentable results of the domination of really able young officers by effete, ignorant, and worn-out superiors who have risen by mere seniority to positions which scientifically and administratively they are quite incapable of fulfilling, by reason of their age and of the antiquated state of their information, if even many of them had ever possessed at any time the qualities or the inclination necessary for such posts. Worst of all, perhaps, is the elevation to the very highest offices, by mere lapse of time and military rules of promotion, of men who are most capable of fulfilling routine duties, but are wholly unfitted to be trusted with the administration of the health and lives of the vast population depending on us in India. What is urgently needed is a Royal Commission, or strong Departmental Committee, to inquire into this whole matter, and to institute a radical change. For at present India is decimated by wholly preventable diseases; the health of our troops is ruined by the same causes. With us lies the reproach of nursing and fostering cholera in what is called its endemic home—a purely ignorant and silly phrase. Until some great change is made in the whole system and of the administration the great sanitary needs of India will never be met. You will pardon me for occupying you with the subject which may seem to be in part foreign to our immediate work, but which is of vast moment to the health of a great population in our Indian dominions.

The Regulation of the Slaughter of Animals for Human Food and the Inspection of Animals before and during Slaughter.

Dr. T. M. LEGGE, in opening the discussion on the Regulation of the Slaughter of Animals for Human Food and the Inspection of Animals before and during Slaughter, said that in his opinion a person who had qualified both in medicine and veterinary science would have been the one most suited to have done so. His only claim to undertake the task was that he had devoted some attention, in the principal capitals of Northern Europe, to the methods adopted for the inspection of meat. Great Britain was in the matter of meat inspection twenty years at least behind Germany, France, Belgium, and Denmark. The explanation was to be found in the fact that veterinary science was at a higher level abroad than in this country, partly because the veterinary colleges there were State supported, and partly because more opportunity was given to veterinary surgeons in the practice of their profession by the numerous appointments given to them as experts on meat. Then, again, public abattoirs having existed for a considerable period of time abroad the need of a scientific control of the animals slaughtered in them had been more felt. The first point he would lay stress on was the necessity for compulsory powers to close private slaughter-houses and to the erection in their stead, in all towns of more than 5000 inhabitants, of public abattoirs. An occupation such as the slaughtering of animals, that was in many of its details revolting, and which might lead if proper care were not taken to grave nuisance, ought to be concentrated as much as possible. The advantages to be gained from centralising this and all the various processes incidental to it—such as gut scraping, fat melting, the extraction of the albumen from blood, &c.—far outweighed in his mind the objections urged on the other side by the butchers. The credit of having introduced public slaughter-houses in France must be attributed to Napoleon I. In Prussia the law of 1868, supplemented by that of 1881, gave the powers to local authorities to compel the butchers to close their private slaughter-houses and slaughter only in the public abattoirs, and making it at the same time a punishable offence to introduce into the city from outside fresh meat without first submitting it to an expert for examination.

After describing very briefly the abattoirs abroad with which he was most familiar (as Paris, Brussels, Berlin, and Copenhagen) Dr. Legge proceeded to the second main point—namely, the necessity for appointing professional meat inspectors, preferably from the ranks of veterinary surgeons, to replace the untrained persons at present charged with the work. He would prefer to leave to the veterinary inspector-in-chief the final decision as to what meat should be condemned or not, rather than to the medical officer of health and a justice. Abroad, as soon as the principle of meat inspection was recognised there never was the least doubt that the persons best qualified to undertake the work were veterinary surgeons, and, speaking generally, in all large towns in France, Germany, and Belgium such persons were the only experts legally recognised on the

Digitized by Google

subject. Reference was made to the sub-inspectors in Belgium and to the examinations they were obliged to pass. An outline was given of the routine method of inspection adopted at the abattoirs abroad and at the stations where the carcases of animals slaughtered outside the town were examined. He then called attention to the unsatisfactory state of the law in Great Britain under which the condemnation of diseased meat was made, and dwelt on the law dealing with the subject in Germany and France. In Germany the Imperial law of 1879 on "the Trade in Food Stuffs" recognised only two kinds of bad meat—(1) that which was injurious to health (*gesundheitsschädlich*); and (2) bad or spurious (*verdorben*). The local regulations, however, that were adopted in such towns as had suppressed private slaughter-houses went much further and chiefly determined the action of the veterinary inspector. Under them the second division of bad (*verdorben*) meat became further divided into—(*a*) meat that was bad in the ordinary sense of the word, and to be treated therefore as equivalent to injurious to health; and (*b*) meat that was bad, but not so bad that it might not be utilised as food, provided its condition was marked as being either "of diminished value" (*minderwertig*) or "defective in quality" (*mangelhaft*). The regulations with regard to tuberculous meat had been considerably modified in Germany by a Ministerial decree issued in 1892, which allowed greater latitude in the consumption of such food. The most important points in it were: 1. The meat of tuberculous cattle must, as a rule, be regarded as dangerous to health (and therefore be condemned) when the muscular tissue contains tubercles or when the animal is wasted, even though no tubercles are found in the muscles. 2. The flesh of tuberculous animals must not be regarded as injurious to health when the tubercles are found—(*a*) exclusively in one organ, or (*b*) when two or more organs being affected, they lie in the same cavity, and are not connected with one another by lymph channels or by bloodvessels belonging to the systemic circulation. Such meat is to be regarded as of first quality and to be sold without any restrictions. The importance of the regulation is seen when it is recognised that section 2 includes about 95 per cent. of all tuberculous animals. Stress was laid on the way in which tuberculous meat was rendered absolutely sterile by steam cooking in the Rohsbeck steam ovens at Berlin. The absence of reference in the reports of medical officers of health to the diseases on account of which meat was seized was mentioned, and attention drawn to the admirable statistics on this subject in the report of the Berlin abattoir. In conclusion, he referred to the report of the Royal Commission appointed to inquire into the effect of food derived from tuberculous animals. It was a matter for great regret, he thought, that the terms of that inquiry did not permit of any report being made as to the administrative procedure available for reducing the amount of tuberculous material in the food supplied by animals to man. Seeing what was being done in Denmark, chiefly through Professor Bang's efforts, in employing tuberculin as a means of diagnosing tuberculosis in cattle, he believed that the matter could not be left where it was, and he hoped that another Royal Commission would be appointed to inquire not only into the preventive measures to be taken against tuberculosis, but the terms of which would be such as to include the whole question of meat inspection.

Dr. H. R. SYDNEY MARSDEN, speaking on the same subject, said that the consideration of the subject naturally divided itself under three heads, namely—(1) treatment of cattle before slaughter, lairage accommodation, &c.; (2) method of slaughter and dressing of animals; and (3) treatment and inspection of the carcase after dressing. Animals should be brought to the slaughter-house as quietly as possible. Proper lairage accommodation should be provided, in the form of enclosed sheds, with good top light and ventilation (side ventilation was too cold in the winter months). The surface of the floor should be flagged and channeled, with a good fall from the head to the rear, so as to keep the standing always dry, and all drains should be outside the building. There should be a plentiful supply of water. The animals should be poleaxed and pithed without delay, stuck immediately after pithing, and the body well bled. All carcases and offal should hang in a properly ventilated, light, clean, and cool cooling-house for twelve hours after slaughter. Most diseases showed themselves at once, and it was important that the meat inspector should see the diseased parts before anything had been done to them to alter their appearance. But there were cases in which the disease was more noticeable after the carcase and offal had cooled; it was therefore important that they should be inspected both before and after cooling. The following diseases showed themselves at once: tubercle, pleuro-pneumonia, peritonitis, anthrax, cystic disease of the kidney, abscesses, Texan fever, swine fever, and puerperal fever; but the disease showed itself more distinctly after cooling as regards colour, smell (or both), &c., in the following cases: Texan, swine, and puerperal fevers, jaundice, most diseases of the kidney, and inflammations generally. A word should be said about the freezing of carcases. No carcase should be put into the refrigerator until properly cooled, the freezing process should then be gradual and not too great, otherwise the carcase sweated again on exposure.

Dr. JOHN F. J. SYKES (medical officer of health for St. Pancras) said that diseased meat must be prevented from being distributed for food. This applied equally to home-killed dead meat and to imported dead meat. The best time to judge of the health of food animals was at the time of slaughtering, when they could be examined during life as well as after death, but above all when the internal organs could be examined together with the carcase and at the same time. In order to facilitate the inspection of home-killed meat the aggregation of slaughter-houses was desirable. In spite of precautions it would be possible to foist upon the market meat of animals dying of disease. In order to prevent this and to take away the inducement to profit by the sale of diseased meat it would be necessary to institute—(1) the systematic inspection of milch cows at periodical intervals by veterinary inspectors; (2) the purchase at public expense of diseased animals and meat before exposure for sale at a price that would materially relieve the owner from bearing the whole loss—in other words, paying compensation; or (3) failing the adoption of this course the compulsory examination and marking of all meat and the prohibition to sell meat without the recognised token or mark.

Surgeon-Major POOLE, M.D. (Norwood) supported Dr. Legg's paper. He entirely objected to private slaughter-houses.

Dr. HILL (Birmingham) advocated the abolition of private slaughter-houses, which were centres of filth and disease, contaminated the sewers, and also enabled the dishonest butcher to hide away carcases which ought not to go into the market.

Dr. SLADE KING, Surgeon-Major PRINGLE, and others followed.

Dr. SYKES submitted a resolution which had for its object the marking of foreign meat; but after some discussion, on the motion of Dr. NEWSHOLME (Brighton), the following was passed as a substitute: "That, in the opinion of this Section, and in view of the fact that the Royal Commission on the Effect of Tuberculous Food on Human Health by the terms of their appointment were restricted to tuberculosis, it is desirable that a Royal Commission be appointed to consider the whole question of meat-supply and inspection. That a copy of this resolution be sent to all the Ministers of State."

The late Visitation of Cholera in Hungary.

Dr. EUGENE FARKAS, District Superintendent of Public Health, Budapest, read a paper on this subject. He said that the cholera epidemic which reached Europe in 1892 had been three times imported into Hungary, in each of the years 1892, 1893, and 1894. In 1892 the Government early in the summer made strenuous efforts to prevent the importation of cholera. Travellers and their baggage were submitted to medical inspection and restrictions were made touching the importation of goods from infected countries, which caused much injury to commerce and trade. In spite of these measures the cholera arrived in Budapest towards the end of September, and there was also a considerable extension in Hungary which followed mostly the course of the rivers. The experience of the cholera in 1892 proved that the restrictions which nearly annihilated commerce were useless. The Hungarian Government abandoned a great part of them in November, 1892. There was also a marked change in public opinion as to the usefulness of general sanitary measures which were formerly neglected. A great many sanitary improvements were carried out, and in this the panic due to the cholera in 1892 had a very great share. So that the epidemic of the year 1893, although imported early in the summer, did not attain great dimensions. In 1894 the cholera was again imported into Hungary, this time to the county of Máramaros. The epidemic lasted here 207 days,

Digitized by Google

but with the exception of this county could not establish a footing in Hungary. Any success could not be expected except by means of general sanitation, as was pointed out by Sir John Simon thirty years ago.

Dr. DUKA congratulated Hungary in having appointed Dr. Farkas, who was acquainted with the ideas of English medical officers of health, to the position of District Superintendent of Public Health of Budapest.

Sewer Ventilation.

Mr. J. PARRY LAWS then introduced a discussion on Sewer Ventilation in a speech in which he showed that the results of modern research have not only enlarged our knowledge of the causation and propagation of infectious diseases, but they have also in many instances shown that the exciting cause of the diseases—namely, the specific micro-organisms—pass out of the body with the bowel discharges, and so gain access to our underground sewers. These facts have imparted to the subject of sewer ventilation a significance and importance unknown in earlier times. To find a thoroughly satisfactory solution to the question, Is sewer air harmless or otherwise? and, If harmless, its modé of action? is of great moment to hygiene, for our attitude with regard to this all-important question must of course be profoundly influenced by the conclusions at which we ultimately arrive. The injurious effects which have been, and still are, attributed to sewer air may arise from three separate and distinct causes:—1. From poisonous inorganic gases, such as sulphuretted hydrogen, and concomitant diminution of the percentage of oxygen in the sewer air. 2. From the organised constituents (the micro-organisms) of sewer air. 3. From the presence of some volatile and highly-poisonous organic compound or compounds, possibly of an alkaloidal nature. Although the hypothesis which regarded sewer air as capable of disseminating the morbific germs of disease is proved beyond reasonable doubt to be an erroneous one, we must not therefore forget the immense benefits and the saving of life that modern sanitation, mainly influenced by this hypothesis, has brought about. Whatever the ultimate verdict be, whether sewer air is harmless or otherwise, it will always be the imperative duty of those charged with the care of the public health to ensure rapid and efficient removal of all sewage and refuse matter, and above all to guard against defective drainage and probable pollution of water supplies. The more light that is thrown upon the dissemination of those diseases which have been erroneously associated with sewer air, the more evident does it become that a polluted water supply, and, as an incidental result, a polluted milk supply, are among our most insidious foes.

Mr. NEECH (medical officer of health for Atherton) related some experiments made on sewers of ordinary size to test the movement of air in sewers. In the experiments on one sewer it was found that when the flow of sewage was very small air moved upwards, while when the flow was larger it moved downwards. In another experiment it was found that the velocity with which the smoke introduced into the sewer moved increased directly with fall of the sewer and the velocity of a body of water passing down the sewer. The question, Mr. Neech continued, might be asked, Ought sewers to be ventilated? A sewer with good even and self-cleansing gradients with perfect air- and water-tight joints and connexions, with house drains efficiently disconnected therefrom, and constructed in a district where there was no possibility of subsidence, probably needed no ventilation other than a few 4 in. pipes at suitable points carried high up into the air to let off any undue accumulation of gases, and equalise internal and external pressure. The conditions connected with many of the older sewers were different. Often they had gradients and were not self-cleansing. They had defective joints and connexions which allowed sewer air to pass into the subsoil, especially when of a gravelly nature; not being able to escape through the surface of paved streets, it tended to be drawn into the basements of houses. There were many drains connected with old sewers the existence of which was unknown, and many others the course of which was uncertain. The joints of such drains were very defective; they often ran near and even beneath houses, and occasionally the sink waste water pipes of some of the older houses were found connected directly thereto. Such a sewer should be ventilated.

Were it possible to extract sewer air with heat and burn it, that doubtless would be the most effectual means of dealing with it from a sanitary point of view, but this appeared not to have been found practicable for general application. A sewer in which the air constantly moved upwards should have the valves inserted at that side of the manhole at which the sewage left it. Then the air moving upwards would escape through the ventilators in preference to the manhole. Valves were useless where the movement of sewer air was variable, but in these cases the air could be filtered as it passes out of the sewer at the street level.

The discussion was continued by Dr. Davies (Plumstead), Dr. Oldright (Canada), Dr. Haughton (Norwood), Dr. Bond (Gloucester), Dr. Groves (Carisbrooke), and Dr. Hill (Birmingham), who thought that sanitarians should direct their attention more to the construction of the sewers. If plenty of oxygen were admitted it did not much matter whether they were ventilated above or upon the ground.

Underground Bakeries.

A joint paper by Dr. F. J. WALDO and Dr. DAVID WALSH was then read dealing with the subject of Underground Industries, with special reference to the Baking Trade in London. The tendency, they said, of civilised communities to flock towards particular centres of population has led to a vastly enhanced value for town lands. Hence the builder, wishing to make the most of his site, not only soars into the sky, but also burrows into the earth. By the London Building Act of 1894 Government laid down certain regulations as to the height of houses outside the City proper. The Legislature, however, has not dealt with underground rooms, except when they are used for dwelling purposes. The main object of this paper is to inquire whether underground rooms can be converted into wholesome workshops. The attention of the writers has been drawn to the subject by an investigation of underground bakeries. Most of these places are nothing more or less than cellars and quite unfitted for workmen. In London, and no doubt in many of the large towns throughout the United Kingdom, many cellars and basement rooms are quite as improperly used as workshops. Until a rigid system of house-to-house visitation is the rule it seems likely that ninety-nine out of every 100 underground workshops will escape any control altogether. After careful consideration the writers have come to the conclusion that an ordinary cellar can be converted into a wholesome workshop. It is true that such a task would involve a good deal of structural alteration and a considerable outlay of money. Among essential points of construction are a height of 8 ft. and minimum of 500 cubic feet for each workman, with a special allowance for gas-jets. Walls must be smooth and kept dry by damp-proof courses and by freedom from contact with outside soil. The window space must equal at least one-eighth of the floor area. Ventilation and light, as well as drainage and lavatory accommodation, must be such as to satisfy advanced modern requirements. The floor must have at least 9 in. of concrete, and any drains passing beneath it must be laid at least a foot deep and cased in a bed of concrete. Water should come from the rising main. In order to make a wholesome basement workshop the writers regard a front outside area as absolutely essential. Further, they would make a second area compulsory, either at the back or the side of the building. The main practical difficulty in satisfying these requirements would no doubt be the making of an area in houses which rise flush from the pavement. In order to meet this objection the writers have devised the scheme of the "borrowed area." The front of the shop is to be carried back some 5 ft. or 6 ft. and an area sunk in the space thus "borrowed," as it were, from the overhanging main building, which is supported by a cross girder. The outside area is thus gained at the expense of a part of the shop and of the basement. The size of the shop is thereby lessened, but by way of makeweight the basement beneath is converted into a light and habitable room.

Dry Methods of Dealing with Urine.

Dr. G. V. POORE, Professor of Medical Jurisprudence and Clinical Medicine, University College, London, then read a paper the object of which was to show how different was the behaviour of urine when mixed with absorbent material to that which it manifested when it was mixed with water or left unmixed with anything. Dr. Poore's experiments went to show that when mixed with absorbent material and exposed to the air it never became offensive, notwithstanding that a good deal of ammonia was developed. He showed a conical flannel bag, 2 feet 6 inches long and 1 foot in diameter at the base, which was filled with about

Digitized by Google

six pounds of dry deal sawdust on May 29th, 1894, and which had stood in his room at University College ever since. Between May 29th and July 26th, 1894, over 39 pounds weight of urine was added to the sawdust. Very little urine was added between July 26th, 1894, and May 1st, 1895; but between May 1st and July 30th, 1895, about 45 pounds weight of urine was added. Notwithstanding that the flannel bag had become so rotten that it would scarcely hold together, the mixture of sawdust and urine was not in the least offensive and had never made its presence in the room felt by any unpleasant smell. Of the 84 pounds of urine added, only 6 pounds had been returned as filtrate, while about 68 pounds had been evaporated or retained. The filtrate had been dark brown, thick, and of high specific gravity, but had never been offensive nor had it shown after lying about for months any tendency to putrefy or become offensive. The sawdust, the urine added, and the filtrate had been analysed by Dr. Kenwood. The results of filtration through other materials, such as earth, cinder and ashes, old stucco, peat-moss litter, and crumpled paper were also given. The results as regards the absence of offensive smell were identical with the above in the case of earth, stucco, and peat-moss litter. When fresh earth, fresh stucco, and fresh ashes were used the filtrate was almost colourless and odourless, but the power of ashes to give this result was short-lived, and after the ashes and cinders had become soddened the filtrate became strongly ammoniacal and offensive. The filtrate from peat was dark-coloured but clear (not thick like that from sawdust), and never offensive. The crumpled paper at first gave a very offensive filtrate, but when it got fairly soaked and really absorbent all offence ceased. The paper became in the process of drying riddled with a fungoid growth (saccharomyces and penicillium), and gradually dried up to a material scarcely, if at all, to be distinguished by the eye or nose from ordinary garden earth. The explanation of the above facts was, in Dr. Poore's opinion, doubtful. It was probable that in the case of deal sawdust and peat the antiseptics contained in these bodies might have had some effect. In the case of the other bodies it was probable that microbial action might have produced the result. As far as he was able to judge from limited experience, sawdust that had been thus soaked with urine became a valuable manure. In contrast with the above a sample of urine which had stood in a glass beaker lightly covered with paper since January, 1895, was exhibited, and was shown to be intolerably offensive.

The Section then adjourned.

PSYCHOLOGY.

This Section met in one of the rooms on the second floor of the Examination Hall, Victoria Embankment, and was presided over by Dr. MICKLE, whose work in connexion with the association of insanity with morbid cardiac conditions, as well as his treatise on general paralysis of the insane, are well known to all who are interested in psychology and the morbid associations of insanity.

Address by the President of the Section.

The Section was opened with an address by the PRESIDENT. After extending a cordial welcome to the members of the Section, he gave a brief account of some recent laborious but highly interesting work on which he has been engaged with reference to abnormalities occurring in the form and arrangement of brain convolutions. It was first pointed out that the figures in many of our text-books are really taken from patients who, from the fact that they had died in infirmaries or State-aided institutions of some kind, might, at least in the majority of instances, be placed in the category of "incapables." He then proceeded to point out various points in which he had found the brains of the insane to be peculiar. These peculiarities, which chiefly consisted in differences in the size and form of the convolutions, were found to be more frequent on the right side than on the left, and the variations were described as occurring in various cortical regions. Care was to be taken in drawing inferences from data confessedly not complete, but on the whole it seemed to be clearly indicated that neglecting cases of insanity in which the tendency to degeneration may be present certain changes in the form and arrangement of the convolutions of the brain in the insane may be found to occur, possibly with some degree of significance in relation to the kind of mental change present.

The Treatment of Melancholia.

A discussion on the Treatment of Melancholia was opened with an exhaustive paper by Dr. HENRY RAYNER, lecturer on psychology at St. Thomas's Hospital. After enumerating the various modes of treatment, an opinion was expressed that open air treatment, with exercise short of actual fatigue, was desirable. Various points of interest were touched upon, and especially in regard to treatment by hypnotics; the author expressed his opinion of their perniciousness, given in a routine way. Considerable stress was also laid upon the desirableness of measures for prophylaxis being taken, especially in those who might inherit some tendency towards mental depression. Regularity in all different ways, especially as regards food, was insisted upon, and also the importance of muscular, even more than of mental, training.

The PRESIDENT conveyed the thanks of the meeting to Dr. Rayner and briefly alluded to a few points raised in the paper.

Dr. BLANDFORD, in criticising the paper which had been read, remarked on the great difficulty of laying down any rule as to the treatment of this disease on account of the different degrees in which it may affect different patients or even the same patient at different times. He expressed a strong opinion against the haphazard way in which patients suffering from melancholia are sent for sea voyages, more especially by those who have never been a sea voyage themselves, and pointed out the almost tempting allurements to suicide which such a voyage would offer. He expressed dissent from Dr. Rayner's view as to hypnotics, regarding them not only as useful but even essential in some cases.

Professor BENEDIKT directed attention especially to cases of melancholia occurring in the female. He also regarded the danger of the acquisition of drug habits as a real one in such cases. He attached importance to electro-therapy in this condition, and to the administration of very minute doses of cocain.

Dr. WEATHERLY laid much stress upon the necessity of having attendants for such cases, capable of gaining and keeping the confidence of the patient. He also uttered a warning against going beyond the "fatigue point" of a patient in the endeavour to give sufficient exercise, and alluded to the frequent presence of some peripheral source of irritation—e.g., hæmorrhoids, and such like—in many cases of melancholia.

Dr. NORMAN KERR alluded to the frequency with which alcoholic indulgence was found in the subjects of melancholia; but he attached much importance to finding the proper food for the individual, and mentioned the case of an old gentleman of eighty-five, without any alcoholic habit, who was always cured of his recurrent attacks of melancholia by the administration of peptonised milk.

Dr. CLOUSTON, after complimenting Dr. Rayner on his excellent paper, alluded to the cause of melancholia as probably a defect in the katabolic processes of the cell, leading to an undue instability in the mental sensory cell. In illustration he instanced a case of a patient frequently but instantly rescued from melancholia by the administration at once of one-eighth of a grain of morphia.

Dr. BATTY TUKE expressed his belief in the efficacy of rest in bed in these cases, and was of opinion that the morbid state of the nerve-cell was not necessarily primary, but might be secondary to a disordered vascular condition.

Dr. NICOLSON also thought that a refusal to allow the circulation some part in the causation of this disease would be a mistake. He referred to the extremely salutary influence which the convalescent patients in the hospital at Broadmoor had upon patients sent there suffering from melancholia.

Dr. DUNBAR in her remarks dwelt particularly on the difficulty that meets the practitioner in dealing with cases in the early stage on account of the ignorance of ordinary physiological laws present in the general public.

Dr. RAYNER replied to the various points raised.

Mental Symptoms in Exophthalmic Goitre.

Dr. MAUDE next read a paper on Mental Symptoms in relation to Exophthalmic Goitre, pointing out that while actual insanity with this disease was rare, a certain degree of mental change—motor restlessness, insomnia, occasionally illusions, with incapacity for mental application, and loss of memory—was almost always present. His deductions were made from observations on twenty cases.

Dr. E. S. REYNOLDS read a very interesting paper on the Mental Symptoms of Bodily Diseases, detailing the various mental states found in association with diseases of the brain, spinal cord and viscera, as well as in those produced by the presence of organic or inorganic poisons.

Mr. HENRY HEAD also read a paper on Mental Symptoms

Digitized by Google

in relation to Bodily Disease in the Sane. From his observations it appeared that visceral disease was associated with cutaneous tenderness and frequently with tenderness in different scalp areas; and there seemed to exist some more or less constant association between the area of scalp affected and the accompanying mental change.

A short discussion then took place on these three papers, in which their great interest and importance were alluded to. Dr. CLOUSTON, Dr. YELLOWLEES, and others took part in the discussion.

PHYSIOLOGY.

Address by the President of the Section.

Dr. DAVID FERRIER, Professor of Neuropathology in King's College, and Physician to King's College Hospital, delivered an address on the Relations of Physiology and Medicine. He commenced by mentioning that he held the position of a physician rather than that of a physiological specialist, and continued:—

In former days few, if any, would have been found prosecuting the study of physiology who were not also engaged in the actual practice of medicine or surgery. Things, however, have greatly changed. Owing mainly to the division of labour, which the progress of knowledge has rendered a necessity, physiology has become increasingly technical, and tended to separate itself more and more from medicine in its practical aspects. Hence there has grown up, more perhaps in other countries than in our own, a generation of physiologists who have little interest or sympathy with the practitioners of medicine; while we have still, and always have had, a class of practitioners who, though acknowledging physiology to be one of the institutes of medicine, say farewell to its problems and methods when once they have passed their examinations and engaged in the practical work of their profession. In both extremes there lies great danger to the best interests of the science of physiology and the science and practice of medicine. The practice of medicine offers not infrequently rare conjunctions of symptoms, and valuable opportunities of research, too often wasted, which a little physiological training on the part of the practitioner might often have turned to good account; and the necessities of practical medicine have been the most fertile source of inspiration of physiological experiment. Much of what might otherwise have remained as vague surmise or, at most, plausible hypothesis has been raised to the level of verified fact by well conceived and often simple physiological experiment. The experimental method is, as it were, the keystone of the arch; indispensable, indeed, to the security of the structure the foundations of which have been laid in clinical observation. In many—perhaps I ought to say most—departments of physiology the experimental method is the most powerful weapon of inductive elimination, but there are problems in the investigation of which the clinical method is indispensable. For instance, almost the whole of our knowledge of the so-called trophic influence of the anterior cornua on the muscles, has been arrived at by clinical observation on the symptoms of anterior poliomyelitis and progressive muscular atrophy in man; and on similar observations has been largely founded our knowledge of the segmental grouping of muscles in the spinal cord, which has only been rendered more precise by experimental research. On clinical research primarily, and to a large extent solely, rests much of what we know respecting the paths of degeneration in the nerve centres inaccessible to the experimentalist, but often within the reach of the morbid processes of disease. The physiology of the ductless glands—namely, the thyroid, the suprarenal capsule, and the pituitary body—rests, for the most part, on clinical research, by which was first established the probable relation between abnormal conditions of these glands and the dystrophies of myxœdema or cachexia strumipriva, Addison's disease, and acromegaly respectively. Of recent work done in this country, I know of nothing more worthy of mention, or which serves better to illustrate the mutually complementary relations of experimental physiology and clinical medicine to each other than the researches of Head on the one hand, and those of Gaskell and Sherrington on the other, in reference to the segmentary relations of the visceral and somatic nerves of the head and body. [Professor Ferrier concluded with a sketch of the results of these two observers, making especial reference to Head's determination of the zones of the head and neck, which are the seat of somatic reference of irritation of the thoracic and abdominal viscera innervated by the vago-glosso-pharyngeal splanchnic nerve.]

Dr. W. H. RIVERS exhibited a Reaction Time Apparatus, by means of which touch and mental associative reflexes could be measured.

Professor DE BURGH BIRCH then entered into considerable detail in describing the Equipment of an Experimental Laboratory, and exhibited apparatus ingeniously modified in some respects from those in general use.

The Results of Section of the Trigeminal Nerve.

Dr. ALDREN TURNER then read an interesting paper on the Results of Section of the Trigeminal Nerve and the consequent Degenerations. The conclusion of practical importance at which he had arrived was that there was no evidence of the Gasserian ganglion having a trophic influence upon the eye, and that, therefore, notwithstanding occasional accidents, its removal need cause no anxiety so far as the nutrition of the eye was concerned. Clinical experience supported this view.

Dr. MOTT and Dr. SHERRINGTON, who joined in the discussion, agreed with Dr. Turner, and the former had found that on animals whose spinal cords were experimentally destroyed ulcerations occurred upon the hind legs but not on the forelegs. This fact he attributed to the less protected condition of the legs and their greater liability on this account to microbic infection.

The Results of Lesions of the Tuberculum Rolandi.

Dr. ALDREN TURNER then further discussed the Results of Lesions of the Tuberculum Rolandi, and illustrated his remarks with lantern slides of sections of the cord at various levels. His results tended to prove that tactile and pain sensations were transmitted by different routes; he aided his contention by reference to a clinical case, and showed a series of slides exhibiting the results of total and partial removal of the cerebellum. Dr. Ferrier and he had found a zone of degeneration in the antrolateral part of the cord after removal of the cerebellum and also a comma-shaped tract of degeneration after removal of one side of that organ.

Dr. ALEXANDER BRUCE of Edinburgh discussed the paper, and remarked that the tracts indicated were demonstrable in the cord of the fœtus.

The Function of the Spleen.

Dr. WILLIAM HUNTER then read a paper on Experiments relating to the Functions of the Spleen. He had used toluïn diamide as a destructive agent in doses of three strengths, and found that in the case of animals in which the spleen was not removed there was evidence of blood destruction in the spleen, splenic vein, and portal vein, while the general venous system was practically unaffected; while in animals in which the spleen had been removed there was little or no evidence of blood destruction in the veins above mentioned, but some evidence of this change in the mesentric veins, the lymphoid structures related to the latter evidently assuming the *rôle* of the spleen.

The paper led to some discussion, in the course of which Dr. Hunter was asked for an explanation of the phenomena he had described, but beyond suggesting that it was probably the result of splenic cellular activity declined to speak more definitely. He considered the action of the destructive agent was indirect.

Dr. MELLUS showed a large series of descending degenerative changes in the brain and spinal cord after removal of a portion of the cerebral cortex at the inferior genu of the fissure of Rolando.

Dr. EDRIDGE GREEN read a paper on The Perception of Luminosity at different parts of the Retina, and endeavoured to prove that the effect of light in the retina was not confined to the spot on which it falls.

A short discussion ensued.

Dr. MARINESCO, who spoke in French, then related his views on Tertiary Atrophy and Regeneration of the Central Nervous System. He advanced a theory of reflex mechanism in explanation of such lesions, and illustrated his remarks by interesting sections of the spinal cord, which exhibited an unilateral and comparative atrophy of all the elements in the affected half.

Dr. SHERRINGTON discussed the paper.

The Section then adjourned.

ANATOMY AND PHYSIOLOGY.

This section was presided over by Mr. HENRY MORRIS Surgeon to the Middlesex Hospital, who, after a few well

Digitized by Google

chosen words, called upon Mr. William Anderson to open a discussion upon:—

Art in its Relation to Anatomy.

Professor ANDERSON commenced by saying that anatomy owed a heavy debt to art, although he might also say that art owed an almost equal one to anatomy. But before anatomy was studied as a science the great masters of Greek sculpture, without any aid from dissection, produced works which were masterpieces of artistic beauty and anatomical correctness, although while sculpture had advanced to such a pitch medicine and surgery were still in a purely empirical stage. Illustrations of some of the great Pheidian statues were thrown upon the screen. The lecturer passed on to consider the decline of classical learning and art, and after mentioning the mediæval treatises on anatomy, which were illustrated in a way from dissections of the lower animals, came to times when anatomists employed the great artists to illustrate their works. Leonardo da Vinci executed a series of anatomical drawings for his own improvement. The work of Berengarius was touched upon, and then came the immortal work of Vesalius, illustrated by a pupil of Titian. Professor Anderson then mentioned the anatomical works of the seventeenth century in the illustrations to which anatomical correctness was subordinated to the debased art of the day. The figures were represented in various affected attitudes standing on pedestals in pseudo-Italian landscapes, holding aside their skin or muscles to show the internal organs. After this, the bathos of both anatomy and art, came the works of Cheselden and William Hunter, the latter of whom wrote the classic work on the anatomy of the gravid uterus. Professor Anderson then briefly referred to the modern methods of anatomical illustration, such as chromo-lithography and "process work."—Mr. HENRY MORRIS then moved a vote of thanks to the lecturer, which was unanimously carried. A large collection of ancient and modern illustrated works on anatomy were on view, the most striking of which was the great treatise of William Cowper, with copper plates by Gerard de Luirens.

PATHOLOGY.

Address by the President of the Section.

Dr. WILKS, Consulting Physician to Guy's Hospital, in a paper on Reparation, said:—

The most evident and most momentous fact in Nature is the incessant change ever going on in the world; in fact, throughout the universe as far as the power of the telescope and spectroscope can reach motion and action never cease. This endless activity in the organic world implies continual growth and decay, or, in other words, life and death. As the earth in its revolutions produces the seasons, so we witness living objects growing up under the influence of the sun's rays, and again decaying as the warmth departs. The higher animals take a few revolutions round the centre of heat, during which time they first grow and then decay; and one of these is man. The variable time in which he endures is determined in great measure by his surroundings, for many of those which are detrimental to him and shorten his days are quite obvious to us; and to study still further his environments and discover their influences for good or evil is one of the most important provinces of the physician. Now just as the body grows and decays as a whole during a term of years, so we may see the two processes of production and destruction going on in its several parts when subjected to any special stimulus, such as an injury or other morbid influence. It is to this subject I wish to draw your attention, for although my own mind has often been directed to it, I think in all that I have written and taught I have failed to lay sufficient weight on the distinction between them. When speaking of any unnatural condition or any adventitious substance found in the body, I have, like many others, employed the term "morbid," and been content with the expression, whereas a little further consideration would have shown that only a portion of what is found would rightly answer to the term, a part only being strictly pathological, whilst the other is a result of a true physiological process; in fact, the simple words disease or morbid imply too much of destruction without a recognition of a corresponding reparation. With regard to injuries, the reparative and conservative conditions are generally clear, witnessed in scars, or where a spine of bone is made to support the fractured shaft of a limb which is united at an angle. In many forms of internal disease, also, we all recognise the reparative process, and have no difficulty in distinguishing the physiological from the truly pathological; for example, in valvular disease of the heart—where we at once perceive how the hypertrophied cavities, are the manifestation of physiological and conservative processes, and in the same manner hypertrophy of the muscular fibre of the uterus, of the intestine, or of the bladder, indicate obstruction in the passages of these organs. There are, however, more complex states where the pathological and physiological changes have gone on side by side and thus make it more difficult to assign to each their due proportion. It may be that the constructive and destructive forces are more intimately associated than we have hitherto conceived, and that a mutual relation may exist between them of an electrical or chemical nature. This was suggested in the remarkable observations and experiments of the Golding-Birds, father and son, who showed that if one electrode be placed on an ulcer the latter will rapidly heal whilst a sore is being produced at the other positive pole. In an ordinary ulcer the two processes are seen going on before the eye, for although the old definition implied a simple destructive process merely, yet we can clearly perceive during the process of granulation and in the secretion that new material is being formed. Mr. Golding-Bird has well said that in an ulcer we see a constructive inflammation, and that there is not merely a loss of tissue, but there is embryonic life going on again—a recommencement of evolution, a redevelopment of growth from elementary cells, the embryonic elements being always present and roused to action by the inflammatory process, so that the two conditions of growth and decay are mutually dependent. This local process is the same which is going on throughout the whole body, where the nourishment is obtained from outside materials, or, as Herbert Spencer puts it, "We grow by reconstructing the elements previously dispersed in animals and plants." It is the same process, indeed, which is going on throughout the world. Naturalists tell us, for example, of the formation and decay of coral reefs; whilst these are constantly growing and being renewed on the surface they are wasting beneath, so that the lower parts consist of nothing but the detritus of the older reefs which have broken up. Growth and decay are thus constantly proceeding, and Nature, with her myriad voices, proclaims the great truth that life is ever ceasing and ever being renewed. In the human being the same processes are perpetually going on, not only in health, but in states so-called diseased, as in the above-mentioned example of ulcer. Yet this double process is continually overlooked, no doubt from the difficulty we have in being able to separate the reparative from the true morbid action. In most instances this is owing to the fact of the reparative material not being equal in organisation and similar in structure to the original tissue. The complex parenchymatous structures are not renewed after injury, like the simpler ones of bone or areolar tissue, although occasionally we meet with a true growth of nerve fibre or adenoid structure. What we generally mean, therefore, by repair is not reparation by a growth resembling the original structure, but by a growth of lower organisable material. Still, the attempt at repair, in whatever way it may be accomplished, is continually visible, and the object of these remarks is to point out not only where we have been remiss in failing sufficiently to recognise the true interpretation to be put upon many of the new changes we meet with in the tissues, but have been content to style them all in a very cursory manner morbid. This distinction has an important clinical side as regards prognosis and treatment, besides being one of pathological interest.

I will endeavour to illustrate my meaning by one or two examples, and will take first the case of phthisis. During a long experience in practice I have seen nothing so common as an error in the prognosis of this disease. And why? Because the constructive changes have been confounded with the destructive ones; in fact, the very signs which the beginner regards as the strongest proofs of disease are those which indicate the probability of cure. He learns the signs of a cavity in the lung, and then, recognising its existence in a particular case, he immediately condemns his patient, feeling instinctively that nothing could be more terrible than the existence of a large hole in a vital organ. And yet a moment's consideration would show him that the dull tympanitic note, the absence of vibration in the chest walls, their sinking in, the pectoriloquy, &c., all point to a hard-walled cavity due to a reconstructive action following the destructive process. The formation of this fibrous tissue has

Digitized by Google

shut off the part destroyed from that of the healthy lung, a reparation and cure have been going on and produced those marked physical signs which he has regarded as indicative of disease. No wonder, therefore, that a mistake in prognosis has been made, and that after condemning a patient who has manifested such physical signs the medical man has been surprised to find him still living years afterwards. I have, indeed, not only seen the mistake made by young and inexperienced men, but by older members of the profession; they have often confessed their surprise on seeing phthisical patients still alive whom they had condemned years before. This case of phthisis is perhaps the commonest example, where the constructive and destructive processes have not been sufficiently distinguished; but we will now take another case, where the changes are more complex, and where a greater difficulty exists in distinguishing those which may be regarded as destructive and those which are reparative. I refer to cirrhosis of the liver. This organ may be observed during life to be first enlarged and then become nodulated and shrunken; amongst other signs of the disease which the text-books describe is an enlargement of the veins on the surface of the abdomen. These were thought at one time to be due to some pressure on the vena cava, but this is really not the case, and the appearance is now shown to be due to an enlargement of the epigastric vein in connexion with the opening up of the old umbilical vein, which often becomes as large as a goose quill. Through this the portal blood flows and finds a free passage into the vena cava and systemic circulation. Injections may be easily made to pass from one system into the other. The patient in this way is relieved from an engorgement of the portal system and from the consequent dropsy. This enlargement of the veins, therefore, which is simply described as a sign of cirrhosis, should also be spoken of as a sign of a reparative character. And probably this is not all, for when the cirrhotic organ is examined carefully and microscopically we find that, although the nodules are composed mainly of atrophied hepatic tissue, there has also been an attempt to replace it by a new formation of cells and vessels. New bloodvessels may be seen and apparently new ducts, as well as cell growth. Now, although these new elements are not perfect enough to take on the function of the liver, there can be little doubt that they do relieve the circulation in a disabled organ. That new hepatic structure may grow under the strain of necessity is seen in those cases where portions of the liver have been destroyed by injury or disease in the same way that one kidney will double its size when its fellow from any cause has become atrophied, illustrating the doctrine of Aristotle that function precedes organisation.

[Dr. Wilks then gave examples where the morbid and reparative processes are mingled, so that it is very difficult to allocate the condition to its right category, and concluded by saying that, as a teacher of pathological anatomy, he had not paid sufficient regard to the distinction between the constructive and destructive processes; that whilst there have been decay and degeneration there have been also growth and regeneration. He held that to study these for the sake of discovering the several influences exerted in the production of each would be of great practical import, tending to show that pathology is governed by the same laws as those which exist in every other department of Nature, and, therefore, may safely take its place among the other sciences.]

The Malaria Parasite.

Dr. PATRICK MANSON then followed with a paper on Some Facts in the Life History of the Malaria Parasite. He commenced by describing the usual forms of the parasite met with in the blood of patients suffering from malaria, and by showing how these varied in their appearances according to the time, during or after the attack, or when they were obtained; he then went on to show how the flagellate forms were not developed in the body, but only outside the circulation; how in their earliest stages they were merely masses of pigmented granular protoplasm, which could be observed to thrust out the characteristic flagellæ, and these eventually separated themselves off from the cell and played an important part in the development of the organism outside the body. He regarded the intra-corpuscular elements as destined to carry on the life of the parasite within the body, whereas the flagellate forms were met with only outside the body. The point as to how the flagellate forms escaped from the circulation next occupied his attention, and he proceeded to quote from the researches of Surgeon-Major Ross to show that probably the mosquito was an intermediate host of the parasite. This observer has found that the parasites are able to resist destruction in the stomach of this insect, and passing thence into the blood occur much more frequently in the flagellate form than in blood drawn from the finger of a patient with malaria; its development in the intermediate host is also evidenced by the fact that the crescent forms all become spheres. He cited an instance of a man who by accident had swallowed the contents of a bottle containing a store of malarious mosquitoes, and who, although he had never had fever nor been exposed to the chance of getting it, yet in eleven days developed malarial disease. He explained the communication of the disease from the insect to man by supposing that the parasites on the death of the mosquito are added to water or soil, and by that means are carried into the human body.

In the discussion which took place Dr. THIN drew attention to the fact that in Sierra Leone malarial fever is very common, but mosquitoes are rare. He agreed with Dr. Manson in that, supposing these insects to be an intermediate host, drinking water probably formed the means of communication to man. He believed that the flagellæ played some part in the life history of the organism, and were not, as Marchiafava thought, due to the convulsive movements of the protoplasm in its death struggles.

In reply to questions from other members Dr. MANSON stated that the parasite must have some third form not yet discovered in which it can remain latent in the body for a long time, until the conditions favourable for its development occur, at which time the patient develops an attack of fever.

Exophthalmic Goitre.

A case of Exophthalmic Goitre was recited in detail by Dr. A. FOXWELL in which marked changes in the brain were found. These were: 1. Chronic inflammation and sclerosis of the pia covering part of the vermiform process and of that covering the fourth ventricle and also of the middle commissure of the third ventricle. 2. Acute softening of the surface of both thalami. 3. Excessive vascularity of the surface of the brain of the internal capsule, of the cerebellum and of the medulla—in the middle of the medulla, at any rate—leading to occasional hæmorrhages. 4. Sclerotic changes involving portions of the tegmen, pyramids, and the nuclei of the fasciculus gracilis and cuneatus, and of the tenth pair of nerves.

Papers were contributed by Dr. G. R. MURRAY on Some Results of Thyroidectomy in Rabbits, by Mr. J. H. TARGETT on Syringomyelia and Joint Disease, and by Dr. ROBERTSON on Arachnoid Hæmorrhage.

The Fungi of Cancer.

In the discussion on Cancer Mr. D'ARCY POWER, Mr. SHATTOCK, and others criticised adversely Dr. Braithwaite's paper, in which he claimed to have demonstrated fungi in malignant disease. They thought that the appearances which he described were due to changes in fat cells and elastic tissue produced by the methods used in the preparation of the specimens, and that the so-called spores were in reality crystalline substances deposited in colloid media.

The following papers were also read before the meeting of the Section terminated:—On the Chemistry of Carcinoma and Sarcoma, by Dr. HEWLETT; On the Insidious Marrow Infection of Breast Carcinoma, by Dr. H. SNOW; the Occurrence of Cancer in Chalk Valleys, by Mr. T. W. BLAKE; On the Condition of the Larynx in a case of Typhoid Fever, by Dr. A. R. PARSONS.

OPHTHALMOLOGY.

Address by the President of the Section.

Mr. HENRY POWER, in his introductory remarks, said:—After the warm expressions of welcome that have been addressed by the President to the members of the Congress generally, little remains for me to add, except that the Ophthalmologists of London in a more special manner greet with a friendly grasp of the hand all those who are practising this important department of medicine in other cities and towns of Great Britain, or who have come to visit us from other countries. I am sure I am expressing the sentiments of the Metropolitan members of this Congress when I say that we feel ourselves to be highly honoured by their presence on this occasion, and that we trust they

Digitized by Google

will not only derive profit from the numerous papers on interesting subjects that have been promised to us, but that they will receive some pleasure from the various objects of interest this great city and its vicinity can exhibit. Half a century ago no such friendly salutation could have been offered, because ophthalmology though full of vitality had not yet reached the stage of separate existence, but was still merged in general surgery, few or none practising it with exclusiveness. Within that period, however, great changes have occurred. Affections formerly lightly passed over or altogether disregarded have been found to require for their explanation and elucidation prolonged and careful inquiry, and new means and methods of research have been added to our previous stock. The ophthalmoscope invented by Helmholtz, the distinguished physicist and physiologist, whose loss we have had so recently to deplore, opened up a vast field of study, and the revelations of the changes presented by the intra-ocular structures obtained by its employment are by no means exhausted. The investigation of errors of refraction and their correction in the path pursued by Donders and his school and still further developed by Landolt and others; the study of muscular anomalies and defects so energetically worked out by our American coadjutors; the recognition of the immense practical importance of good colour-vision in all forms of land and sea conveyance regulated by a system of signals; the labours of a host of clinical observers both at home and abroad in devising and perfecting methods of treatment both operative and medicinal; the gradual recognition of the fact that many constitutional diseases—such as albuminuria, diabetes, leukæmia, and febrile affections—generally powerfully influence vision, are all circumstances that have contributed to enlarge the horizon and to develop the resources of the ophthalmologist to an extraordinary degree. This, again, has led to the founding of several special hospitals devoted entirely to the treatment of diseases of the eye, and also to the establishment of departments with the same object in view in connexion with each and all of our general hospitals. To discharge the duties connected with these institutions professors have been appointed who have required the services of assistants and house surgeons and these in turn have been able to instruct a large number of intelligent and diligent students, and thus to diffuse throughout the kingdom a sound knowledge of the nature and treatment of eye diseases; so that, whereas only a decade or two ago the unfortunate victim of iritis or keratitis, squint, cataract, or glaucoma, residing in the country, was either compelled to go to London, Edinburgh, Dublin, Manchester, Birmingham, or one of the great centres of population, at the present time there are few towns of very modest size that do not possess an ophthalmic surgeon capable of diagnosing and treating any of the ordinary forms of ophthalmic disease.

The foundation of the Ophthalmological Society of Great Britain has proved of the greatest utility by enabling remarkable cases to be seen by all who are interested in the subject by supplying a field where papers can be read in which new views can be advocated or old ones subjected to wholesome criticism, and in which an *esprit de corps* can be fostered and a fellow feeling established amongst men who have no petty jealousies but who seek success only by honourable rivalry. Our branch of work is by common consent the most fortunate of all in the opportunity it affords of applying methods founded on pure science to the diagnosis and treatment of disease; and so long as our ranks are recruited by those who have gone through the ordinary curriculum of medicine and surgery now required by the examining bodies, and so long as it is recognised by the profession generally that an accurate knowledge of it will often supply the key to many constitutional affections we need have no fear that it will separate itself from them to become a barren branch. But this does not the less relieve us from the necessity of constantly keeping in view the scientific side of its study. Perhaps from the recognition of my own defects, I am strongly of opinion that all those who enter the ophthalmic department of the profession should have gone through a sound mathematical training. At the present moment this is certainly not a *sine quâ non* for a candidate to any post at an ophthalmic hospital, but I am sure that if it were made so it would be of great advantage to the rising generation of British ophthalmologists, that the practical work would be better done, and that under any circumstance it would prove useful mental training.

Though the organ with which we are engaged is but small it is yet a theatre large enough to permit many pathological processes to be followed out which owing to the diversity of tissues present can be defined with more precision than elsewhere, where theories of the nature of disease can be tested, and where different modes of treatment can be strictly compared and their relative value estimated. Immense strides have been made in the diagnosis of ophthalmic disease during the last fifty years. In 1842–43 Dr. Hocken tabulating the statistics of six eye infirmaries,[1] states that out of 30,971 cases of ophthalmic disease, 16,383, or more than half, were cases of conjunctivitis. A very different distribution would obtain now-a-days. No doubt much remains to be done; there are many gaps and imperfections in our knowledge; let us hope that some of these may be filled up and removed in the labours to which we will now address ourselves.

Acromegaly with Ocular Complications.

Mr. ARTHUR BENSON read a paper on the Ocular Complications of Acromegaly, about which, he said, little was definitely known. He quoted the case of a farmer aged thirty-eight, a big man of 12 st., who developed with the signs of acromegaly central scotoma and loss of colour vision in the temporal halves of the retina. The man smoked a good deal, and great improvement followed giving up tobacco and taking iodide of potassium. Later there was almost complete loss of vision, which returned in seven weeks under thyroid extract given in the fresh state, but there remained a defect in the upper temporal quadrant of the retina on each side. Dr. Benson referred to the enlargement of the pituitary gland and its pressure on the chiasma as the cause of visual defect.

Dr. MEYER said that in most of the cases the outer half of the field of vision was lost owing to pressure on the posterior part of the chiasma, but the modifications of vision were very various. He thought the improvement scarcely corresponded with acromegalous atrophy.

Mr. LITTLE (Manchester) quoted a case in a young woman in which contraction of the field took place outwards and upwards; there was atrophy of the optic nerve in the left eye.

Professor PANAS (Paris) mentioned a case in a woman of thirty-five in whom acromegaly was associated with temporal anopsia and epileptic fits. Treatment had no effect.

Mr. SWANZY instanced the case of the Irish giant, Cornelius McGrant (1720), whose skeleton was preserved at Trinity College, an examination of which showed it to be affected with acromegaly. The sella Turcica would contain a walnut. The posterior clinoid processes and the commissoral groove were obliterated, and sight must have been limited to the outer portion of the left retina.

Professor FUCHS said the central scotoma might have been due to the acromegaly, and quoted an instance of tumour of the optic nerve causing central scotoma in the absence of alcohol or tobacco. Subsidence of œdema would account for improvement taking place.

Mr. HILL GRIFFITH and Mr. SNELL also spoke.

Certain Rare Cases of Recurrent Ophthalmia.

Professor FUCHS read a paper on this subject, of which he had seen twenty-three cases. Coarse injection of the conjunctiva of the globe and episcleral vessels occurred, accompanied by pain on movement and photophobia. There was also in some cases removal of the near point, or spasm of accommodation, with temporary myopia. The conditions recurred at intervals of a week or fortnight, and affected both eyes alternately. Uric acid and oxalates were in excess in the urine. The disease appeared to be associated with gout, rheumatism, or malaria. Salicin and quinine delayed the attacks, which recurred when the drug was left off and seemed to be precipitated by catarrh. He quoted several cases at length.

Dr. BERRY referred to the cases under the term episclerites fugax. The vessels only were affected. There was no glandular change. The disease corresponded closely to Von Graefe's subconjunctivitis, and sometimes went on to iridocyclitis or sclerotitis. It was best treated with salicin or hydropathically.

Mr. E. MORGAN JONES said that after other remedies had proved unsatisfactory he had performed peritomy with good results.

Dr. JOHN GRIFFITHS and Mr. HERN mentioned cases of an allied nature which were accompanied by a vesicular eruption at the margin of the cornea.

[1] THE LANCET, Aug. 19th, 1843.

Digitized by Google

Mr. GEO. WALKER had secured immediate relief in these cases by radiating incisions through the conjunctiva across the affected area.

Mr. PRIESTLEY SMITH thought the condition was difficult to define. There was a strong superficial resemblance between the episcleritis urticarial conditions—hay fever and herpes eruption. He regarded the malady as depending on constitutional state, like gout or rheumatism, and considered the elimination of the waste products as of the first importance, and this was much assisted by taking hot water freely the first thing in the morning and at other times.

Mr. CRITCHETT agreed that this was identical with Von Graefe's subconjunctivitis. He thought the best treatment was to give salicylates and quinine, with hot water internally and systematic bathing—both water and hot air.

Professor FUCHS, in reply, said the condition in question must be clearly distinguished from vesicular eruptions—catarrh or injury of the cornea. In the acute stage he had used Vichy water with some benefit, but the problem was to prevent recurrence.

Chlorine Water in Threatening Suppuration of the Vitreous.

Dr. BERRY described this treatment and cited some striking cases which had been so treated, in accordance with the results of Chassaud's experiments. It was the safest and least irritating antiseptic and produced immediate effect. Four drops of a 4 per cent. solution were introduced with a hypodermic syringe into the centre of the vitreous—through the sclerotic between the insertions of the external and superior recti. It was specially useful in suppuration, traumatism, and sympathetic ophthalmia.

Dr. ARGYLL-ROBERTSON said he had seen some of the cases described, and had been favourably impressed with the method. The chlorine produced no ill effect, and it was worthy of more extended employment.

Mr. NETTLESHIP thought in cases of traumatism the chlorine water might better be injected along the track of the injury.

Dr. BERRY, in reply, said the wound was commonly in a position inadmissible for operation, and further, as the currents in the eye were directed forward, it was better to inject the fluid from the back.

Dr. BULL (Paris) read a paper on Optometry by the Subjective Method. He said it involved many sources of error, but one especially consisted in the disturbing effect of *astigmia* (*sic*) while determining the degree of myopia. All astigmia, he said, should be made myopic, the vision then being tested for distance.

Dr. ANGUS MCGILLIVRAY cited a curious family history of astigmatism, which, occurring in a male parent, slipped the next generation and appeared in the males of the third and fourth generations, being transmitted by the females like hæmophilia or pseudo-hypertrophic paralysis. He also quoted instances of family nystagmus.

Dr. KOSTOR described the construction and use of an instrument for measuring the tension of the globe.

Mr. LEE described a case of Pemphigus of the Cornea, with total destruction of vision.

Mr. BELL referred to a similar case.

M. GAYET illustrated the use of photographs in different positions of the eye to compare the parallelism of the optic axes before and after operation for squint.

Mr. JOHN GRIFFITH read a paper on the Pathological Distinctions between Sarcoma of the Choroid and Glioma of the Retina.

DISEASES OF CHILDREN.

The proceedings in this Section were opened by a few remarks by the President, Mr. J. H. Morgan, relating to the history of the Section since its establishment in 1883.

Congenital Syphilitic Manifestations in Bones and Joints.

The first discussion, on Congenital Syphilitic Manifestations in Bones and Joints, was then introduced by the President, who summed up in an admirably clear and judicious paper the present state of our knowledge with regard to this important group of cases. After touching on the chief historical points in connection with the subject, Mr. Morgan described the various pathological processes which underlie the different manifestations. He pointed out that in infants the changes are found chiefly at the growing end of the bones, especially at the distal ends, and are more frequently met with in the humerus and tibia than in other bones. There is an endosteal inflammation, which not infrequently goes on to suppuration. Clinically there is general thickening of the bone, especially towards its distal extremity; occasionally there is deformity from displacement of the entire epiphysis, and frequently there is "pseudo-paralysis," the limb being flaccid and never moved by the patient if he can avoid it. With all this there is seldom much pain unless suppuration has occurred. When this occurs the synovial cavity of the joint is apt to become involved through spread of the inflammatory process. In older children, after the second dentition, frequently at the same time as keratitis, we have a different manifestation of the disease. Nodes are developed on long bones, and necrosis often follows, and there is a tendency to general hypertrophy and induration. It is in these cases that necrosis of the palate and bones of the nose is due. There is very little nocturnal pain in these cases, but they are not nearly so amenable to iodide of potassium as are similar conditions in adults. These cases of osteitis not infrequently lead to alterations in the shape of the bones, curving, lengthening, or in some cases shortening from interference with epiphyseal growth. Dealing with the changes in the cranial bones and with the relations of congenital syphilis to rickets, Mr. Morgan strongly repudiated Parrot's doctrine that rickets was merely a stage of congenital syphilis. He held, however, that rickets was mainly due to improper feeding, and that hereditary syphilis was frequently a predisposing cause of the condition. With regard to "bosses" on the cranium, he held that the majority were due to hereditary syphilis, but he evidently considered it still an open question whether bossing of the skull and craniotabes were due to direct syphilitic processes or whether it was only "by impairing nutrition and acting as a debilitating factor that it is prominent among many others as a cause of rachitic changes." With reference to syphilitic manifestations in joints he pointed out that many were due to extension of the epiphyseal inflammation, and that in others there was chronic effusion into several joints, usually symmetrically, concomitant with interstitial keratitis, as Mr. Clutton has described. These cases are very chronic, and there is no pain.

In the interesting discussion which followed, in which Dr. Barlow, Mr. Eve, Mr. D'Arcy Power, Mr. H. B. Robinson, and Mr. H. Stansfield Collier took part, there was a general agreement with the President's account of the conditions present. With reference to the vexed question of the significance of craniotabes and cranial bossing Dr. Barlow stated that he had been obliged by his observations to entirely give up the opinion he strongly held and taught—that these lesions were necessarily indications of syphilis. Although admittedly these signs are most frequently met with in cases of congenital syphilis associated with rickets, they also occurred in children in whom the possibility of hereditary syphilis could be excluded; and, further, that they appeared in the crania of young animals suffering from rickets. He regarded congenital syphilis as a powerful predisposing cause of rickets by modifying the nutritional processes; but, like the President, he scouted the idea that ordinary rachitis was a syphilitic process.

The Nervous Sequelæ of Infectious Disease.

Dr. HENRY HANDFORD then introduced a discussion upon the Nervous Sequelæ of Infectious Disease. He said:—

The occurrence of paralysis during convalescence from the continued fevers was known to Cullen and many of the older writers, but it was not until the time of Landry and Gubler that the doctrine of post-febrile paralysis assumed a definite form. For the sake of clearness it seems useful to divide the sequelæ into those affecting—(1) the brain and its membranes; (2) the spinal cord and its membranes; (3) the nerves; and to consider in regard to each division, first, the changes which may occur after all or most infectious diseases, and, secondly, the special qualities of the changes resulting from particular diseases, that is, first, generically and then specifically.

1. It would indeed be strange in a complex machine like the organ of mind, the orderly working of which is so readily disturbed during the pyrexia of fever, especially in childhood, if it did not sometimes, as a result of that disturbance, become permanently deranged. And so we find; but such cases are rare, except when the brain is by inheritance weak and unstable. I recollect one case of mania with delusions

Digitized by Google

arising during convalescence from enteric fever. Idiocy and imbecility are occasionally met with from arrested development in the very young, and melancholia, dementia, and a few cases of mania in older life. Scarlet fever and enteric fever are the most frequent antecedents. Epilepsy has resulted from attacks of most of the specific fevers, especially scarlet fever, measles, and typhoid fever in that order of frequency. More cases of epilepsy are said to be consecutive to scarlet fever (apart from the influence of nephritis) than to all the other acute diseases put together. Optic neuritis may follow scarlet fever, and a condition of speechlessness—not a true aphasia—is not uncommon after typhoid fever. Meningitis may arise in the course of any of the acute specific diseases, more especially small-pox, measles, and scarlet fever; but its presence is much more frequently suspected without sufficient cause than overlooked. When present it is often probably septicæmic in character. 2. Both myelitis and spinal meningitis are occasionally produced by attacks of infectious disease. Sometimes it appears to be of septicæmic origin, but in many cases the specific poison of the fever seems to be the exciting cause. Acute myelitis especially follows small-pox, measles, and scarlet fever. It may arise in the course of the fever, during convalescence, or a month or more after the disease is over. Numerous cases of anterior polio-myelitis have been described after acute infectious diseases, but no doubt in some of them the muscular wasting has been primary and in others due to peripheral neuritis. Nevertheless, a residuum remains where the wasting has in reality been caused by an affection of the nerve cells. Numerous cases of Erb's juvenile form of progressive muscular atrophy have been described arising after measles, and last year I had under my own care a case of the same disease in a boy aged eleven arising after an attack of enteric fever, and much aggravated by a subsequent attack of scarlet fever. The exact influence of the infectious diseases in determining the onset of muscular atrophy is difficult to define. The usual occurrence of the disease in several members of the same family shows that a congenital tendency must be called into activity by the virus, but the numerous instances where the disease has followed immediately upon one of the acute specific fevers also show that the influence of the fever poison cannot be altogether neglected. In some cases the weakness due to an attack of typhoid fever seems to persist in the legs, and is accompanied by neuralgic pains and various defects of sensation. It is supposed that the symptoms may be due to disseminated myelitis of slight intensity. The muscular tremor, which is occasionally so conspicuous during the course of typhoid fever, may continue during convalescence, and it has been known to persist and to be followed by symptoms of disseminated sclerosis. 3. Peripheral neuritis follows especially diphtheria, influenza, typhoid fever, measles, and small-pox. In 1888 I published three cases after typhoid fever: in each case there occurred extensive anæsthesia in the distribution of the ulnar nerve (preceded in two of them by pain and tenderness), wasting of the small muscles of the hand sufficiently extensive to be easily demonstrated by photography, reaction of degeneration, paralysis of motion, together with local fall of temperature and nutritional changes in the skin. In one of the three, and in several other cases also, I observed a remarkable tenderness of the toes sufficient to require them to be protected from the pressure of the bedclothes by a cradle. In one case the arms also were tender. In others there has been remarkable hypersensibility of the skin both to touch and more especially to cold. In most of these cases, perhaps in all, neuritis was the cause of the symptoms. There are still several extremely difficult though important problems awaiting solution. Among them are—the nature of the poison, which, circulating in the blood or lymph, acts immediately upon the nervous tissue and causes paralysis; whether there is one virus or whether there are many; whether the resulting lesion is inflammatory or (mainly) degenerative; and whether there are specific differences in the sequels of each infectious disease. Although there is scarcely any acute infectious disease a severe attack of which may not be followed by a lesion or disorder of some portion of the nervous system, yet with such various antecedents there is a very strong general resemblance between the sequels. The chief reason of this resemblance, no doubt, consists in the fact that the manifestations of the nervous disease depend almost entirely upon the organ and tissue affected, and very little upon the virus producing the lesion. I doubt if it is possible to distinguish by the symptoms a neuritis following enteric fever from one following small-pox or measles. But just as in the toxic neuritis due to lead, arsenic, or alcohol there is evidence of selection—and some nerves are much more frequently attacked than others—and as in diphtheria the toxine very rarely indeed attacks the spinal cord, while it affects the nerves in 25 per cent. of all cases, showing special affinity for the nerves of the palate, so in the nervous disorders which follow the other acute infectious diseases there is likewise evidence of selection. After some diseases the brain is most frequently affected, after others the spinal cord, and after yet others the peripheral nerves; but why do not the nervous sequels which depend on the toxic effect of the fever poison follow every severe attack? The organisms which produce the toxine produce also the antitoxin; and the affection of the nervous system may depend on the proportion of one to the other, or it may be necessary for various adventitious circumstances to coexist. And, lastly, does the same toxine attack the various portions of the nervous system—brain, cord, or nerves—indifferently?

OTOLOGY.

Address by the President of the Section.

Sir WILLIAM DALBY, Consulting Aural Surgeon to St. George's Hospital, said:—In consequence of the meeting of the International Otological Congress, to be held at Florence in September, we shall not have the assistance of many Continental visitors who otherwise would have come to this meeting; but, on the other hand, Scotland, Ireland, and the provinces will, I believe, be represented more completely than is usual at our annual gatherings. The programme is before us, and besides papers of considerable interest we shall have the privilege of hearing from Professor Macewen, whose brilliant achievements in cranial surgery are so familiar to us, his views on the grave questions involved in operative measures which become necessary when the process of inflammation has proceeded from the middle ear to the cavity of the cranium. In regard to the treatment of the various forms of "nerve deafness," I wish to say that the words in which this discussion have been described were not chosen without due deliberation. The term "nervous deafness" is intended to include not only disease of the nervous apparatus, but loss of hearing due, as we know it to be, to causes which affect the whole nervous system generally; also loss of hearing due to shock or to emotional and mental influences. Lastly, those conditions which, beginning as they do within the tympanic cavity, and at first simply interfering with the conduction of sound, finally are found to involve the perceptive as well as the conducting media, and to be the starting point apparently of subjective nervous phenomena. In short, the title of the discussion has been made purposely vague in order that when the subject of treatment is discussed it should be incumbent on the speaker to be exceedingly definite as to the precise nature of the cases for which the treatment is proposed, for in debating or writing upon so difficult a question nothing is so obstructive to real progress as dealing with generalities. What we desire is to thoroughly thrash out the subject, so that we arrive at the approximate value of various methods of treatment which seem to require a more complete accuracy as to the conditions which they are supposed to combat. We know that we are often unable to point to a definite organic change within the nervous apparatus, but at least we wish to be able to point to the *modus operandi* of the remedy upon the function of the special sense. This anxiety for a more firm basis on which to place various remedies applies especially to the use of pilocarpin and electricity. At one time great hopes were entertained in the profession as to the value of pilocarpin, and yet when the subject was discussed at a recent meeting of this Association at Newcastle it found very little support, even from those who had given it a fair trial. Again, it cannot fail to have been observed how in many nervous disorders great temporary benefit has followed the use of electricity, but the permanent effects have very frequently not been maintained. We hope at this meeting to hear something definite as to the real value of both these agents, and to receive some helpful suggestions as to the conditions, if any, where they may be expected to prove useful. It is noteworthy that in our list of papers we have none upon a subject that must incessantly agitate the minds of aural surgeons. I refer to the operative proceedings upon

Digitized by Google

the tympanic membrane and cavity of the tympanum for the relief of chronic change; for, notwithstanding all the disappointments in this direction, the fact remains that some of us (and I include myself in this number), after years of careful observation, are still in a position to make a selection of cases in which we are reasonably confident that if we could make a permanent and large opening in the tympanic membrane the hearing would be restored to a most useful extent. It is, I believe, in this complete knowledge that the impulse is to be found for all the operations that have from time to time been proposed. It is to an incomplete knowledge in the selection of cases that the great proportion of failures have occurred. Impressed as I am with the brilliant future of surgery in all its departments, I cannot but believe that some day or other (it may be at a distant date) one of us is destined to solve this much-debated problem.

PHARMACOLOGY AND THERAPEUTICS.

Address by the President of the Section.

Sir WM. ROBERTS, late Professor of Medicine in Victoria University, read the following address on Anarcotine, a neglected Alkaloid of Opium. He said:—During my travels in India last year, as a member of the Royal Commission on Opium, I heard a good deal about anarcotine and its employment in years gone by as a febrifuge in the treatment of the malarial fevers which are so prevalent in that country. By far the most abundant alkaloids of opium are morphine and anarcotine, and while morphine represents the anodyne and hypnotic qualities of the drug, anarcotine represents, as I shall presently show, its antimalarial qualities. There are considerable differences in the proportion of morphine and anarcotine in the several varieties of commercial opium. These differences are especially pronounced in the case of Smyrna opium, which is used in this country for medicinal purposes, and Bengal opium, which is popularly used in India. These differences are set forth in round numbers in the subjoined table:—

—	Smyrna Opium.	Bengal Opium.
Morphine	8 per cent.	4 per cent.
Anarcotine	2 per cent.	6 per cent.

It will be observed that Bengal opium is comparatively poor in morphine but very rich in anarcotine. Smyrna opium, on the other hand, is very rich in morphine and very poor in anarcotine. Anarcotine was brought into prominent notice in India about fifty years ago. At that time quinine became very scarce and dear. The supplies of bark from South America were failing, and it had not yet been proved that the quinine-bearing cinchonas could be cultivated with success on the uplands of India. There was thus a serious prospect of a dearth of quinine in India, and the Indian medical authorities had to cast about for some cheaper and more abundant substitute. Now, opium had long been held in high repute among the natives of India as a remedy and protective against malarial fevers, and habitual opium-eaters were said to enjoy a remarkable immunity from malarial infection. Attention was therefore directed to anarcotine, which is the most abundant alkaloid of Bengal opium, and trials were made of its curative power in malarial fevers. Sir William O'Shaughnessy, in 1838, brought the subject before the Calcutta Medical Society. He gave an account of thirty-two cases of intermittent and remittent fevers treated with anarcotine. Of these, thirty-one were cured. He also mentioned 100 other cases which had been treated by his pupils and colleagues with equal success. These results, and others of a like character, induced the Indian authorities to institute further experiments, and, these proving favourable, they caused anarcotine to be prepared in quantity at the laboratories of Ghazipur and Patna, and distributed to the medical depôts throughout British India. Two important communications on the antiperiodic powers of anarcotine lie buried in the medical archives of India and deserve resuscitation. They are based on a large experience, and they prove incontestably that anarcotine is scarcely inferior, and in some classes of cases is superior, to quinine as an antiperiodic. The first, from Dr. Palmer, is contained in a letter to the Director-General of the Indian Medical Department, and is reprinted in the "Proceedings of the Opium Commission," vol. v., p. 78.[1] In 1857-59 Dr. Palmer treated at Ghazipur 546 cases of malarial fever with anarcotine, in doses ranging from 1 to 3 grains. Of these, 541 were cured and only 5 died. In addition to these 546 officially reported cases, he treated with anarcotine a large number of other cases of malarial fever, amounting in all to little short of 1000 cases. Summing up his general experience, he states that in 70 per cent. the fever was arrested at the second paroxysm after the medicine was administered; in 20 per cent. the arrest was equally sure, but was not quite so quick; and in 10 per cent. the medicine did not appear to have any curative effect. He further remarks that there are cases where anarcotine is decidedly more efficacious than quinine—namely, where there is an intolerance of quinine, and where quinine has been given without any effect for a long time. The second communication is a "Report on Anarcotine," by Dr. Garden, which is printed in the seventh volume of the "Indian Annals of Medical Science." Dr. Garden succeeded Dr. Palmer in civil charge of the Ghazipur Station in 1859; and at that time a severe outbreak of intermittent fever, of quotidian and tertian type, had to be dealt with. Taking advantage of the opportunity he subjected anarcotine to an extensive trial. He treated altogether 684 cases, and gives details of 194. Of these 194 cases, 187 were rapidly cured by anarcotine. It only failed in 7 cases, or 3·6 per cent. It, moreover, cured some cases where quinine had failed. The doses he employed ranged from 1½ to 3 grains. He expresses his general conclusions in the following words: "That it [anarcotine] is equal in value to quinine I do not pretend to say, but that it has a claim to the next place in the ranks of antiperiodics is, I think, an undoubted fact." Anarcotine continued in large demand in India for several years, and was regularly supplied from the Government factories at the rate of about a hundredweight per annum. It is to be observed that Dr. Palmer and Dr. Garden perceived a distinction between quinine and anarcotine, and recognised that there were cases of malarial fever which resisted quinine but yielded to anarcotine. Both observers also noted that in a certain percentage of the cases anarcotine proved wholly ineffective. These discrepancies are probably to be explained by the facts brought to light in recent researches on the infective organisms of paludal fevers. It has been shown that these organisms are of more than one kind, and that each kind corresponds to a particular type of malarial fever. There seems to be valid evidence that in anarcotine we possess a second antiperiodic of great power, analogous to, but not identical with, quinine; and the point I wish to press upon those who have opportunities of studying malarial fevers, especially upon investigators in India, is the desirability of subjecting anarcotine to a fresh examination, with a view of ascertaining its value, as compared with quinine, in the different types of malarial infection, and in cases where quinine has proved ineffective. I should mention that anarcotine was originally named "narcotine" by its discoverer, Derosne, and this is the name by which it is still generally known. This designation is, however, wholly inappropriate and misleading. The extensive trials made with this substance in India show that in a pure state it is quite devoid of narcotic properties. For this reason Dr. Palmer renamed it anarcotine. Dr. Garden adopted this suggestion, and I think it desirable to follow his example. I show you here two fine samples of anarcotine. One was manufactured in London by Hopkin and Williams, of 16, Cross-street, Hatton-garden; the other was procured by Dr. Vaughan Harley from India, where considerable unused stores of anarcotine still exist in medical depôts.

LARYNGOLOGY AND RHINOLOGY.

Address by the President of the Section.

Dr. FELIX SEMON, Physician for Diseases of the Throat, St. Thomas's Hospital and National Hospital for the Paralysed and Epileptic, took for the subject of his address "The Post-Graduate Teaching of Laryngology." He said:—Before we enter upon the important general discussion of to-day's proceedings I should like to engage your attention for a few minutes with the question of the post-graduate teaching in laryngology and rhinology in this metropolis. It cannot be denied that post-graduate instruction, such as given at the present time in these two branches, is inadequate

[1] Copies of the Proceedings and Report of the Opium Commission have been deposited in the libraries of the British Medical Association, the Royal College of Physicians of London, and the Royal Medical and Chirurgical Society.

Digitized by Google

to both the opportunities and the requirements of London. The present arrangements are excellent in many respects, so far as they go, but I contend that they do not go far enough, and from conversations I have had with the President and Secretary of the London post-graduate course itself I have come to the conclusion that this opinion is shared by some of the officers of that institution. Clinical lectures on selected chapters of rhino-laryngology, accompanied or followed by the demonstration of a few cases, are all very well, but nobody will learn from such clinical lectures alone to properly diagnose and treat throat and nose cases when they later come under his own observation. For this purpose a much more methodical instruction is necessary.

Another point of considerable importance is the fact that the post-graduate course as at present constituted consists in a combination of a few hospitals in which every special branch is represented by one hospital only, whereas experience has shown that those who wish to take part in the post-graduate instruction appreciate nothing more than the option of an extensive selection amongst various teachers.

Finally, successful competition with foreign post-graduate courses is rendered almost impossible by the fact that the laryngological and rhinological clinics in almost all the general and special hospitals, as well as in the post-graduate course, clash with one another, in that the days and hours of attendance and of lectures are the same in all these different institutions, so that those who would like to condense into a short span of time such post-graduate instruction as they require find no opportunity to utilise their time in a really satisfactory manner.

[Dr. Semon here dwelt on the necessity for efficient and harmonious organisation. He proceeded:]

What we require is something not competing with, but supplementing, the existing institutions, an organisation which aims at providing practical instruction within a comparatively short time not only for the Continental, American, and Colonial visitor, who at present passes by our shores and prefers to put up with the inconvenience of receiving such instruction in another than his mother-tongue, but, above all, for the wants of the British practitioner who, after a short acquaintance with practical work, finds gaps in his knowledge which he considers desirable to fill up, provided this can be done without too great a loss of time. It would be very difficult, I believe, or indeed impossible, to effect such an organisation if it were limited to one special branch alone; but it should be possible to create it if teachers of all the branches in which special post-graduate instruction is required—such as ophthalmology, otology, laryngology and rhinology, dermatology, bacteriology, &c.—joined hands to found it. My own ideal in this respect would be an institution conducted very much, though not slavishly, upon the lines of the Viennese post-graduate instruction, occupying a large house situated as centrally as possible, and provided with a sufficient number of rooms to allow of quite a number of classes in different subjects being held simultaneously. The courses in the different branches ought to begin and to end simultaneously, and to be limited to six weeks, or at the utmost to two months. Every special branch ought to be taught not by one teacher, but by quite a large number of them, it being made a condition whilst the plan is on its trial that the teachers in each branch should agree to hold their classes at such times as not to clash with one another. So far as our own branch is concerned, its foremost aim ought to be to give practical instruction in the use of the laryngoscope and rhinoscope, in diagnosis of throat and nose diseases, and in the technique of those applications which every practitioner ought to be able to effect himself. Clinical lectures, &c., ought only to come in as a supplement, but not as the mainstay of the course. No monster classes ought to be held if really practical instruction is to be given. It will be hardly possible for a single teacher to really instruct more than twelve pupils at one and the same time. As to the appointment of teachers, no question of seniority or of fame, or of an official position at one of the general or special hospitals, ought to give a monopoly in this respect, but everybody should be welcome who could satisfy the board of directors that he is a fit and proper person for teaching the branch in which he proposes to give instruction. The material would, of course, have to be provided by every teacher from his own hospital or other sources, a number of specially selected cases being brought for each day's work. I do not see why it should be impossible to realise in London what has worked with such splendid results in Vienna; and I recommend to all who are interested in post-graduate instruction my plan for further thought and improvement.

DERMATOLOGY.

The President, Dr. RADCLIFFE CROCKER, opened the proceedings with a few remarks apropos of the great variety which dermatology offered to the student of pathology.

On the Pathology and Treatment of Pruritus.

Professor MCCALL ANDERSON (Glasgow) opened this discussion, reading a short and practical paper dealing, in the first instance, with the anatomical features of the skin and their relation to the feeling of itching, then with the usual conditions in which itching is prominent, and finally with the treatment of this very troublesome symptom.

He was of opinion that the portions of the nervous apparatus of the skin specially concerned with the sensation of itching are as follows: (1) the free nerve terminations in the epidermis; (2) the small groups of cells taking the form of a cup and connected with nerve filaments situated in the deeper layers of the epidermis or upper layers of the true skin; and (3) each hair, in virtue of the fine medullated nerve fibres which form a network in the outer coat of the hair and terminate in its sheath, is more or less of a tactile organ, and it is probable that irritation of the hair may cause pruritus. It is very difficult to say, however, why pruritus is such a prominent feature of some diseases of the skin and generally absent in others, such as the strumous affections; how it is absent in the earlier and present in the later manifestations of syphilis—points to which he specially directed the attention of the section. He then spoke of some of the more prominent causes: that which occurs in old age and which he attributes to the circulation of impure blood; that which occurs in connexion with some cases of jaundice; that which comes on in gouty persons and in connexion with functional derangement of internal organs, especially the digestive organs; that which occurs in diabetics; that which occurs in connexion with cold weather (pruritus hiemalis); and finally that which is dependent upon mental and not upon physical causes. From what he said it may be gathered that, without denying the influence of reflex irritation in the production of pruritus, he was of opinion that most cases are dependent upon direct irritation of the nerve terminations in the epidermis. Before entering upon treatment he emphasised the importance of being quite sure of the diagnosis, eliminating all other disorders, such as urticaria, phthiriasis and scabies, in which the itching is but a symptom. Having done so we must make a careful examination of the patient in the light of its etiological factors, and endeavour to correct any derangement which is found to exist. If the itching still persists, then the disease must be treated empirically. After referring to the subordinate importance of most local applications, and to the use of tincture of gelsemium and cannabis indica (Duhring) and carbolic acid (Hebra) internally, he expressed his preference for the employment of electricity, atropia subcutaneously, or the coal tar derivatives, such as antipyrin and phenacetin, in gradually increasing doses. If there is any suspicion of nervous or nutritive debility, nerve tonics, such as phosphorus, arsenic, or strychnia, alone or in combination, may be tried, the last two preferably by subcutaneous injection.

Dr. H. G. BROOKE (Manchester) first remarked on the term "pruritus," distinguishing this symptom from the term "prurigo," used in reference to conditions in which the secondary lesions from scratching are prominent. He preferred to use both the terms in such a generalised meaning as is now universally accepted when the word "lichen" is mentioned. The symptom of itching was then considered from the physiological aspect and its anatomical substratum located in the epidermis, both Dr. Brooke and Professor Anderson mentioning the significant fact that a wound itched while the epithelium was growing over its surface, not while it was in the stage of granulation. The opinion of Bronson, who considers itching to be a perversion of the sense of touch, was quoted, and served as a basis for an analogy between the altered sensation of touch, which we recognise as itching, and the physiologically-developed sensation of touch subserving the sexual emotion. The paroxysms of pruritus that occur in certain diseases requiring violent scratching to produce relief were compared to the sexual orgasm, and the analogy adduced by collateral evidence of complex nerve

Digitized by Google

states underlying both of these modified touch conditions. The importance of some method of classification of the various causes of pruritus was emphasised, and the reason of the difficulty of making such a scheme accurate was mentioned; for in many cases, as has been so often observed, it is impossible to say whether the itching is the primary condition, or, on the other hand, follows a skin lesion which may have been slight or have even passed unnoticed. The following arrangement of causes was advanced as being approximately accurate:—1. Internal. In this category is placed the purely *nervous pruritus*—the primary pruritus of French authors. The tendency of the French school to deal much in "nerves" was alluded to, and the symptoms of "lichenification," so frequently described as a result by French authors, was looked on as some indication that their many cases of purely nervous pruritus may be due in some instances to a primary skin lesion. That pruritus may occur, however, without lichenification was not denied—e.g., in cases "Pruritus sine Prurigo" of some authors—a condition occurring in the old, though also occasionally among the young. Other causes of certain localised varieties of pruritus were mentioned on the occurrence of seborrhœa as a cause especially mentioned—e.g., in genito anal pruritus. The occurrence of the purely nervous itching was then described more in detail, and the speaker considered it to be a "diathesis of itching," demanding external manifestation, and accompanied not infrequently by internal metastases such as hay fever. Other forms of nervous itching, the expression of organic nerve disease, alienated mental states due to reflex causes, &c., were also placed in this division. The influence of various poisons in the blood—e.g., in gout, jaundice, diabetes, rachitis, foods, and drugs, was considered as occupying a place in this part of the scheme. 2. External: This division was more readily dealt with, many of the causes—e.g., local skin diseases and parasitic skin diseases—being visible and more readily dealt with. But Dr. Brooke drew attention to the fact that the local cause might be very insignificant, although its effects by means of reflex nerve irritation were manifested over a wide area, frequently in a very severe degree. The pruritus due to changes in temperature was dealt with in this place, and much interesting evidence adduced to show that changes in blood-pressure were frequently the cause of irritation of the skin in many apparently dissimilar conditions. The importance of the relief of the symptom of pruritus was emphasised, and it was to be recollected that its treatment could be properly undertaken only when the underlying causes were taken into account.

After a few remarks by Dr. EDDOWES showing the relations of symmetrical parts of the body by reflex nervous mechanism,

Dr. MYRTLE (Harrogate) spoke of the difficulty of treatment. Remedies beneficial to one patient were noxious to others with apparently similar affections. The coal-tar preparations and chloral were remedies that in his experience were the most generally useful. Although in certain cases of obstinate pruritus the application of potassa fusa, in solution of 15 gr. to 60 gr. to the ounce, over the affected areas produced great relief.

Dr. WALDO (Bristol) mentioned that in certain cases the application of blisters over the spine, in situations corresponding to the affected areas of the skin, frequently availed much in treatment, while in the peculiar variety of pruritus associated with osteo-arthritis the exhibition of sodium salicylate was to be recommended.

Dr. STOPFORD TAYLOR (Liverpool) felt that in the majority of cases internal medication was of no avail, while much benefit could be obtained by carefully adapted exercise, diet, and general hygienic precautions. The present epidemic of cycling had brought to his notice many cases of pruritus ani among those no longer in the first blush of youth, and he advised the precaution of wearing proper clothing, while the use of spirituous lotions gave much relief. The use of potassa fusa, he thought, could be necessary only in very severe cases.

Mrs. GARRETT ANDERSON remarked on the nervous pruritus so frequently observed in women, and in men who led lives approaching in their conditions those of the women under consideration. She thought that the cause was to be found in the insufficient, improper, and monotonous diet indulged in by these persons, while often at the same time they were engaged in mentally exhausting and sedentary occupations. In the treatment of these cases she advised that the diet suitable to the individual should be found and double the quantity usually consumed ordered to be taken. A rest of an hour before dinner proved most beneficial, while the substitution of silk instead of woollen or linen underclothing should be advised when possible.

Dr. BARENDT (Liverpool) advised careful consideration of the details of all local treatment in pruritus to secure, as far as possible, the accurate carrying out of any plan adopted. In his experience the application of a 2 per cent. solution of carbolic acid in olive oil for five minutes at a time has produced strikingly good results. In certain other cases blisters over the spine had been of service.

Professor MCCALL ANDERSON then summed up, and concluded a very interesting and instructive discussion.

Pityriasis Rubra.

Dr. JOHN LIDDELL (Harrogate) read a paper on two cases of Pityriasis Rubra Pilaris (Devergie), illustrated by photographs, coloured drawings, and microscopic specimens. One of them was that of a girl about fifteen years of age, who had considerably improved under resorcin ointment. A careful study of the histology of the skin had been made, and Dr. Liddell came to the conclusion that the essential change in the disease was an exaggerated keratinisation of the root-sheath which gave rise to the cup-shaped elevations so characteristic of the disease. There was also an increased formation of hairs which was due to a nipping off of portions of the rete connected with a follicle, which itself gave rise to a fresh hair follicle. There was atrophy of the sebaceous and sweat glands. Masses of cells which Dr Liddell described as "parasitic" were also found in the corneous layer.

Dr. ALLAN JAMIESON (Edinburgh) and the PRESIDENT took part in the discussion, the latter remarking that it was a curious fact that the disease, which was undoubtedly a somewhat rare one, had been extremely rare since the death of Dr. Tilbury Fox, only six cases having come under his notice since that time. It was important not to confuse this disease with lichen planus and lichen acuminatus, although both flat and conical papules occurred in this disorder.

A discussion on the Pathology and Treatment of Pruritus was introduced by Professor MCCALL ANDERSON (Glasgow) and Dr. H. A. G. BROOKE (Manchester).

Dr. PYE-SMITH read a paper on the Affection of the Skin occurring in the course of Bright's Disease. Willan had long ago observed a disease, which he called erythema laeve, to be associated with dropsy. Four kinds of skin disorder had come under Dr. Pye-Smith's notice with this relationship: 1. A bright red diffused rash, of general distribution, but generally sparing the hands and feet. 2. Another kind of erythema, having a different distribution and more or less localised. In these the skin was dry and harsh. 3. A moist dermatitis resembling eczema. 4. A diffuse desquamative dermatitis, resembling the exfoliative dermatitis of Wilson, but still more like the pityriasis rubra of Hebra. These occurred chiefly in connexion with tubal nephritis, and were unknown in lardaceous disease of the kidney. They all had the common characters of being superficial and bearing no traces; were acute or subacute in their course and did not tend to recur; they were never pustular in character, though boils were apt to arise independently: they were occasionally, though rarely, purpuric; and, lastly, were usually unattended by itching and other subjective symptoms. The prognosis was not in his experience modified by the occurrence of skin complications, though they generally arose in the incurable stage of renal disease. He did not regard them as of uræmic origin, but associated rather with the neuro-retinitis and serous complications so common in renal disease. They generally arose in patients beyond middle age, and yielded readily to external remedies.

The PRESIDENT remarked that his experience led him to regard these complications as of uræmic origin, as greatly adding to the gravity of the case and as having a markedly lethal tendency.

Dr. SAVILL, referring to the desquamative complications of renal disease, said that his subsequent experience of the epidemic skin disease had led him to believe that renal disease constituted a marked predisposing cause to contract this disorder. Out of five or six cases which he had seen of these diseases concurrently not one had recovered, although the patients were in other respects favourable subjects for the skin disorder. He therefore regarded it as a most serious complication.

Digitized by Google

Dr. PYE-SMITH, in reply, gave reasons for not regarding these complications as of uræmic origin. The exfoliative variety was rare in his experience, but he thought it might very likely be related to the epidemic skin disease described by Dr. Savill.

Dr. PATRICK MANSON gave a demonstration on the Guinea-worm. After a brief description of the anatomy of dracunculus medinensis or guinea-worm, Dr. Manson pointed out that the views formerly held with regard to the way in which this parasite obtained access to the human body were erroneous. He showed that the guinea-worm parted with her embryos before she quitted the human host, and that the process could be provoked by simply pouring a little cold water on the limb in the neighbourhood of the guinea-worm ulcer. The water seemed to act as a stimulant to the worm, which could thus be induced to contract and expel the young through her mouth, the uterus being prolapsed for an inch or two. In this way Dr. Manson obtained a large supply of embryo guinea-worms and repeated Fedschenko's experiments with cyclops quadricornis, confirming the results of the Russian naturalist and somewhat extending them, and showing that the English cyclops was an efficient intermediate host of this parasite. The young guinea-worms on escaping from the uterus of the parent swim about in the water until they encounter a cyclops. They then attack the crustacean, boring their way between the ventral plates until they get into the body cavity. Here they move about quite freely, as many as ten or twenty lying together in the body cavity, and not apparently inconveniencing the cyclops. The embryo now casts its transversely striated integument along with the swimming tail, the latter giving place to a short conical stump. Later a second moulting takes place, eventuating in a tripartite tail, increase of size, and a somewhat more elaborate alimentary canal. The parasite enclosed in the cyclops is then transferred, probably in drinking water, to the human stomach. From the stomach, after digestion of the cyclops, the guinea-worm is supposed to work its way into the connective tissues of its host, and in the course of time to attain sexual maturity. Dr. Manson deprecates interference with the guinea-worm until she has emptied her uterus of embryos. He pointed out that she then tends to come out spontaneously. He also thinks that the new treatment by injection of perchloride of mercury solution in the neighbourhood of the guinea-worm sore may be useful in killing the worm and procuring her aseptic absorption. Four microscopic preparations were exhibited and also some lantern slides, showing the embryo guinea-worm in its free state, in the body cavity of cyclops, and at the conclusion of metamorphosis, seventy days after the parasite entered its intermediate host.

Dr. JOHN GALLOWAY gave a demonstration of lantern slides illustrative of the Pathology of the Skin Affections, chiefly vesicular and bulbous eruptions which arise in syringomyelia, based on two cases which he had observed. One of these cases had been attended in the early stage with the usual perversions of pain and heat sensations, and later developed trophic affections of the skin. The other had developed great deformity of the hands consequent on trophic changes in the phalanges and nails. Dr. Galloway attributed these and the skin changes to local causes.

After a few remarks from the PRESIDENT and Dr. SAVILL,

Dr. A. J. HARRISON narrated two interesting cases of Verruca Necrogenica, which had not, however, so far as could be discovered, had any origin in a post mortem examination or handling of dead carcases, such as is usual in these cases.

ETHICS.

Address by the President of the Section.

Dr. W. F. CLEVELAND, Consulting Physician to the Kilburn Dispensary, read an address, in which, after claiming that ethics cannot be neglected as a subject because they do not form a science, and quoting the views of many of the best known ancient and modern philosophers on the conduct of life, he came more particularly to medical ethics by saying:—In that branch of ethics with which we are more particularly concerned there can be little doubt that the *lex non scripta* has ever been highly efficient for the guidance of those members of the profession who could be styled in the true sense of the word gentlemen. But what has been euphemistically called "the difficulties of general practice"—a term which crystallised into plain language means too often "the struggle for existence"—has altered the general aspect of medical ethics. Keen competition arising from various causes, among which may be mentioned the overcrowded state of the profession, advanced general sanitation, which lessens the demand for our services, and the tendency among the educated to prescribe for themselves, and among the poorer classes to seek advice gratuitously or in the cheapest market, has for years been engendering a greater or less amount of moral laxity among our brethren, and so it has come to pass that a medico-ethical code has been framed with the view of correcting the errors of those who, through ignorance or carelessness or ambition, might be drawn from the path of rectitude and professional honour. Such a code or collection of rules and laws was first drawn up by Dr. Percival in 1807, and this has, with but slight alterations, formed the basis of the subsequent code of the American Medical Association, as well as that of the well-known and excellent work of Mr. Styrap. Now it would only be uttering a truism to contend that the ethics of our profession can be made to turn on any other pivot than that which is embraced in the great moral precept, "Whatsoever ye would that men should do unto you, even so do unto them." It may, I presume, be taken for granted that the civilisation and social development of the nineteenth century have created a platform for practical or applied ethics, and that a code, founded on the observations and experience of those who, by their position in the profession, are worthy of our respect, is not only necessary but likely to be appreciated. But it goes without the saying that for a medico-ethical code to work or bear fruit it is not only essential that we should acquaint ourselves with its rules and directions, but that we should show a ready allegiance to them while they remain in force: for, I take it, as reasonably might we expect a number of artisans or agricultural labourers, who had never seen a compass or studied a chart, to navigate a ship from London to New Zealand, as the members of our profession, in the present complex relations of society, to pursue their course with ethical precision without the aid of the written as well as the unwritten law. As in physical science Nature must be constantly interrogated or made the subject of experiment, so, in order to keep a medico-ethical code up to date, or make it suitable for ethics viewed as a progressive science, we must interrogate history and society, especially that portion of the latter occupied by our profession, and we must note with an open mind the experience of others as well as our own. By such means we may hope to deduce conclusions from which laws for guidance may be ultimately obtained. Under the term "medical ethics" is comprised such a large number of interesting questions that the attempt to discuss all of them on this occasion could not fail to be disappointing. In our programme we have selected some of the more prominent ones, in the hope that they may engage your best consideration, and that a friendly and dispassionate consensus of opinion regarding them may be arrived at, which shall have its proper weight and influence on the mind of our large Association and of the profession generally.

In conclusion, gentlemen, I would remark that we are living in a practical age—an age in which few projects are undertaken that have no *cui bono* in them. Now, what is the *cui bono* of this our Ethical Section? Shall I be too sanguine if I say we hope, through its means, to assist in raising the general status of the profession? In my opinion we shall do so if we can only make it our resolve to uphold, as far as possible, the reputation not only of our friends, but also of our legitimate or qualified competitors, when it is attacked, rather than by significant silence or innuendo to depress them to a level below ourselves. Depend upon it nothing sinks the profession in the estimation of the public more than their observance of the fact that too often we are a body pretending to a regard for honour and etiquette amongst ourselves, while our conduct proves that we are far from being at unity within ourselves. Again, may we not hope, as an outcome of this conference, to stimulate the cultivation of more friendly feelings towards each other, and thereby conduce to that equanimity and satisfaction which every right-minded person enjoys who is on good terms with his neighbour? And, lastly, may we not discover a *cui bono* in the very publicity that is given to ethics by the holding of this Section? Is not our meeting together on this occasion evidence of the conviction that a medico-ethical code to which we can agree is essential for our guidance in the fulfilment of those rights and duties which we owe to each other, ourselves, and the public?

Intra-Professional Etiquette.

Mr. T. GARRETT HORDER (Cardiff) then introduced for debate the subject of Intra-professional Etiquette. After expressing his great satisfaction at the formation of a section of Ethics he pointed out that the loyal and faithful observance of the rules of intra-professional etiquette had an importance which could scarcely he over-rated. It was absolutely necessary that medical men should show mutual consideration and sympathy, else they could hardly expect to escape unfair treatment on the part of the public. Moreover, if patients were made acquainted with the general rules which govern our professional life they would be more likely to avoid courses which tend to place medical men in unpleasant positions. The subject might be conveniently classified under three headings: (1) The etiquette of private practice; (2) that of club appointments; and (3) that of consultation. In the first place, there is no question as to the right of patients to change their medical attendants. In cases of incurable disease there is a natural anxiety on the part of sufferers to try every means which promises relief; they go from one practitioner to another, and it is from such patients that quacks extract large sums, for these gentlemen are troubled by no doubts or misgivings—their remedies are infallible and their charges are liberal. Before accepting a patient who has already been under the charge of a brother practitioner, we should make sure that the previous attendant has been informed of the intended change, and it is a good plan ourselves to communicate with him directly. When consulted by patients who are also members of a club, we should do nothing to embitter the relations between a club medical officer and his patients. Club practice is difficult to carry on, and becomes much more so when it is known that other medical men are willing to accept the office. With respect to the etiquette of consultations, it must be remembered that the relations between the public and specialists have undergone a great change. Formerly the consultant communicated the result of his examination to the family practitioner, but patients now consult specialists without making their intention known to their ordinary attendant. As a general rule, however, the consultant should enter into communication with the family practitioner. For meeting the cases in which the consultant has contrived altogether to supplant the previous attendant it is most desirable that a court of appeal should be instituted by which ethical questions might be examined and decided.

Mr. LEE (Cork) said that some time ago the medical officers of all the medical clubs in Cork resigned their appointments in consequence of abuses whereby wealthy persons were permitted to become members of clubs and obtain medical attendance for seven-and-sixpence a year. The appointments are now held by four imported medical men, whom the profession in Cork do not meet in consultation, and some anxiety is felt by the latter as to their proper course in the event of their attendance being requested on account of dangerous illness (such as post-partum hæmorrhages) among the patients of the club practitioners.

Dr. PEARSE said that the same question had arisen at Portsmouth, where there is an enormous medical club connected with the Dockyard. He thought that no such consultations should be held.

Mr. H. HEMMING urged that in any course that might be adopted due care should be taken that the lives of patients were not endangered.

Drs. HARRIS, WOODS, and MCNEE also took part in the discussion.

Advertising.

Dr. G. W. POTTER read a paper on Advertising. Having defined professional advertising as the public or private praising of a man in his professional capacity by himself or his agents for fame or gain, he observed that it is a vice from which the most highly placed members of the profession are by no means free, and that it is unreasonable to expect the man who takes 2*s.* fees to be ethically precise while the 2-guinea consultant advertises boldly and unashamed. No method of advertising is worked more energetically than the compilation of books. Can it be seriously maintained that the large number of medical works issued from the press are *bonâ fide* intended for the information and instruction of medical men? Some time ago a practitioner persuaded one of his patients to purchase a book which he had written. The price was a guinea, the book was highly technical, and no injustice is done to the author by assuming that his object was to advertise himself and his merits to the patient and the patient's friends. Another device was the leaving of cards at private residences, and a third was in connexion with newspaper paragraphs relative to the illness of prominent individuals. Some of these announcements were unobjectionable from the friends' point of view, but in too many instances the qualifications and the residence of the medical attendant were given with a fulness which left no doubt as to the ulterior motive. Another class of advertisers are the men who give certificates to vendors of foods and other commercial articles. These certificates are duly published in newspapers with many cunning additions. One gentleman in his widely advertised testimonial to the excellence of a certain food inserted the statement that it had been used by many of his influenza patients, of whom he had attended seven hundred without losing one. Another form of medical advertising which is very common and on the increase is the writing of books with catchy titles, which make a great show (of course with the author's name) in the publishers' lists given in the lay press. Needy practitioners in poor neighbourhoods seek to draw attention to themselves by methods of which the better class of tradesmen would be ashamed. There is a special demerit in professional advertising which must be plainly recognised both in order that no injustice may be done to our profession and in order that the public may be enlightened on the subject. The state of the case so far as it concerns the public is that the professional advertiser can by no means guarantee the results of treatment which are at least suggested in his advertisements. A commercial advertiser undertakes to deliver a certain article, and does so, whereas a medical man can only guarantee services—results he cannot guarantee. From the professional point of view, the advertiser takes an unfair advantage of his professional brother who does not advertise.

Unqualified Assistants.

Mr. GEORGE BROWN read a paper on Unqualified Assistants. He commenced by remarking that when he first entered the profession thirty years ago the employment of unqualified assistants was an ordinary proceeding, and that he himself while still a student had been assistant to a medical man. In various ways he came to see the disadvantages of the system, and in 1874 THE LANCET[1] published a letter written by him, the outcome of which was the formation of the Medical Defence Union, with Dr. (now Sir) Benjamin Ward Richardson as president. He (Mr. Brown) was for many years secretary of this association, and had ample opportunities of witnessing the results of unqualified practice. In some cases it was carried on with considerable success, the practitioners having been originally assistants to medical men under whom they had acquired much proficiency in the details of practical work. The system, however, abounded with opportunities for abuse, mainly in connexion with the working of branch practices not under the immediate control of the qualified principal, and there appeared to be no means of effectually dealing with the evil. It used to be said that the General Medical Council was concerned only with medical education and registration and not with such questions as this; but since 1886 the Council has taken notice of very gross cases of the employment of unqualified men, and several practitioners have been removed from the Register under the clause of the Medical Act which refers to infamous conduct in a professional respect. The employment of unqualified assistants is inadvisable both on personal and professional and public grounds. Examples of personal injury due to this cause are to be found in the cases where the purchaser of a practice fails to secure his predecessor's patients because the unqualified assistant, having lost his situation through the transfer, persuades them to put themselves under the care of some other practitioner, even one who may have been brought into the district by the assistant himself. Unqualified assistants who have been discharged have also been known to levy blackmail on their late employer on the ground of irregularity in certificates which the assistants themselves have partly filled up. In the second place, it is hardly necessary to remark that through the competition of unqualified assistants young medical men find it difficult to obtain employment, and are driven to such unprofessional courses as the distribution of handbills, and the formation of dispensaries. But the evil is greatest on public grounds. Many cases of permanent loss

[1] THE LANCET, Nov. 14th, 1874.

Digitized by Google

of health, or even loss of life, are attributable to unqualified practice. An enormous responsibility rests upon principals who render such things possible, and it is our obvious duty to discourage in every possible way the employment of unqualified assistants.

Mr. BRINDLEY JAMES continued the subject, expressing a somewhat more favourable view of the unqualified practitioners, and Drs. GREENWOOD, JOHN BROWN, and BRIDGWATER took part in the subsequent discussion.

THE CLINICO-PATHOLOGICAL MUSEUM OF THE BRITISH MEDICAL ASSOCIATION.

[FIRST NOTICE.]

Situated as it is at the very top of the Examination Hall, and with scarcely any announcement in the official publications of the Association, there are probably few who have done justice to the magnificent collection clinical and pathological material, gathered with so much pains into this temporary museum. We propose, therefore, to notice with some detail, first, the exhibits of morbid anatomy; secondly, the bacteriological exhibits; and, lastly, the patients who were shown each day.

Some idea may be gathered of the wealth of pathological material collected when it is mentioned that nearly all the museums of the Metropolis were visited and placed under contribution; and great credit is due to Messrs. Edgar Willet and J. H. Targett, who were charged with this enterprize. A descriptive catalogue, numbering 84 pages, adds greatly to the value of the collection.

The first Section, dealing with the results of operations on the urinary passages, illustrates the value of collecting a number of specimens from different sources. Nos. 1 to 24 are kidneys removed by operation, mostly with successful issue, for various forms of disease, amongst which may be mentioned cystic sarcoma, adenoma, hydro- and pyonephrosis, due chiefly to calculi, tuberculous disease (the case, a girl of seventeen, making a perfect recovery). It is interesting to note in passing that these specimens confirm the well-known fact that malignant disease (both sarcoma and carcinoma) is liable to involve the kidney in early life as well as beyond middle life, the major portion of the patients ranging from twelve months (sarcoma) to nineteen years, the others being from forty years upwards. Next comes a series of three very perfect specimens from different museums illustrating hydronephrosis of the kidney and dilated ureters consequent on calculus impacted in the bladder, stricture of the urethra, and congenital phimosis (a youth who died at seventeen).

The next series illustrates the results of operations on the alimentary canal, in which direction surgery has made such notable advances during the past year or two. Eleven specimens illustrate the results of gastro-jejunostomy, chiefly for malignant stricture, the patients surviving for periods varying from three days to eight months. In three of these Senn's bone-plates were used. In the case which survived three days the plates were still present, but in those who lived five and eight days they had entirely disappeared. Several cases of pylorectomy and resection of other portions of the alimentary canal for gangrene, injury, and disease are exhibited—a study of which is very instructive as to the different sutures and methods employed. Some lived for four months and longer periods, one of them (resection of cæcum for carcinoma) dying of double pneumonia nine months afterwards. One is a relatively successful suturing of the stomach after perforation of a simple ulcer. In another case of pylorectomy the patient only died two years later from influenza. One of the many dangers is revealed in another specimen, which was successful in the first instance, but the Murphy's button in passing down the intestine caused ulceration and perforation of the intestine ten inches below the resection, resulting in death twenty-eight days after the operation.

Specimens 82 to 91 illustrate the results of operations on the vermiform appendix, and the various foreign bodies and concretions around them which give rise to inflammation in and around this structure. Most of these cases made good recoveries. A large number of gall-stones and specimens of the various injuries to which they give rise form part of the collection. Many of these were large enough to result in intestinal obstruction, some were removed by cholecystotomy. Some were found post-mortem in the right pleura after death, whither they had passed by ulceration and caused empyæma. One large gall-stone, measuring four inches and a half in circumference, was successfully removed by enterostomy. These large gall-stones, more commonly than is generally supposed, give rise to intestinal obstruction, and a collection is shown which were passed per anum.

The next series is a remarkable collection of foreign bodies which had passed through, or been impacted in, the intestines, such as a dessert spoon, a button hook, several tooth plates, an egg cup, and a porcelain jar measuring two inches in diameter. The latter had been inserted by the patient into the rectum to allay anal itching. Its removal was only effected after abdominal section and other procedures, which set up a fatal peritonitis.

Various new growths and other lesions of the larynx are well represented, and include the left ala of the thyroid cartilage removed for carcinoma from a well-known legal gentleman, who survived the operation seven years.

Diseases of the joints are not numerously represented, but the specimens are of great interest, for they illustrate syphilitic lesions. They present the very characteristic appearance of deep crescentic erosions of the cartilaginous surfaces, with sharp edges, having a worm-eaten appearance. Altogether six specimens of this rare and interesting condition have been collected from the Royal College of Surgeons, St. Bartholomew's and St. Thomas's Hospitals, and the private collection of Mr. Davies-Colley.

Specimens 191 to 245 form a very perfect series of intracranial tumours of great interest in view of the attention now paid to this department of surgery. All of these repay careful study, but we have only space to notice a globular fibroma measuring nearly two inches in diameter, occupying the motor centres of arm and leg in the right hemisphere of a patient who died of double pneumonia. There were absolutely no symptoms referable to brain disease during life, a fact which only receives partial explanation from the slow-growing nature of this tumour. Six specimens illustrate simple cysts of the cerebellum, the origin of which disease is still a matter of dispute. Tumours of the spinal cord are also well illustrated, with the exception of syringo-myelus, of which there is only one specimen.

An excellent series of injuries to the epiphyses is to be found in numbers 264 to 282, and a very complete set of specimens illustrating various fractures of and injuries to the neck of the femur has been lent by Sir William Stokes which, unfortunately, arrived too late for mention in the catalogue.

Illustrations of all the lesions known to arise from actinomycosis, both in man and animals, have been collected from all available sources, and next to them come thirteen bottles of Madura hands and feet, a disease closely allied to, if not identical with, actinomycosis—another example of the care and scientific knowledge with which these specimens have been selected and arranged. Then, in natural order, come a series showing the various tuberculous, anæsthetic, and trophic lesions of leprosy, and another foreign disease, Ainhum, endemic to the west coast of Africa, which produces constrictions and loss of fingers and toes, resembling leprosy in all respects, except that the parasite differs notably in its form and life-history. Some perfect specimens of bilharzia hæmatobia conclude the Foreign Section.

Nos. 335 to 364 illustrate hydatid disease of almost every viscus in the body—liver, brain, lung, heart, peritoneum, spleen, kidney, spine, long bones, &c.—and show the various stages through which these diseases pass and the accidents to which they may give rise. Rare tuberculous affections, chiefly ulceration, of the stomach, peritoneum, pleura, tongue, and other organs are also exhibited. Nos. 379 to 407 form a series of congenital affections of the heart, not only patent foramen ovale, which is most common, but all other known conditions.

Specimens of acromegaly and the constant concurrent conditions of enlarged pituitary body follow next, and then a series of the senile symmetrical thinning of the calvarium, together with a specimen of the same condition in the ourang-outang, which is one of the reasons for refuting the supposition that this change arises as a consequence of syphilis or the carrying of weights on the head.

Specimens of the bones in Barlow's disease (scurvy rickets), hermaphrodism, gynæcology, the injuries to infants during parturition, and a large series of calculi removed by Mr. Henry Morris, and lent by the Middlesex Hospital, complete a pathological collection of which, for the purpose of

Digitized by Google

interest to the practitioner as distinct from a purely educational series, London may well be proud.

We propose to notice next week the bacteriological and clinical portions of the museum.

THE MUSEUM.

The exhibits of the twenty-eighth annual museum were shown for the most part on the first-floor of the examination-hall—for the most part since, owing evidently to the great number of applications for space, some were assigned a place in the rooms of King's College, while the curious and unique collection of medical, surgical, and pharmaceutical antiquities exhibited by Messrs. Oppenheimer were set apart in the Victoria rooms of the adjoining Savoy Hotel. This collection, which attracted so much attention, has been made by Dr. Luigi Sambon of Rome, who, under the instruction of the Italian Government, has commenced a work on the History of Medicine for presentation at the next meeting of the International Medical Congress. The collection is chiefly composed of surgical instruments, which date from the first to the fifteenth century, and terra-cotta votive offerings of ancient Italy. Of more modern times, but of equal interest to the visitors, was the case exhibited by Messrs. Burroughs, Wellcome and Co., containing the famous Jenner relics. Amongst them were a portrait and miniature of the discoverer of vaccination, a small medicine cabinet, hair from the tail of the first cow that furnished virus for vaccine inoculation, lancet cases, vaccine points, and the chair in which Jenner breathed his last. Further on was to be seen the case of instruments which belonged to and was carried through Africa by Dr. Livingstone, and other medical relics connected with this great explorer. A still more recent relic shown by this firm was the famous Stanley chest, which contained the medicines employed in the Emin Relief Expedition. Except for some illustrations of ancient surgical instruments and methods shown amongst a few others by Messrs. Southall Brothers and Barclay (of Birmingham), there were no other exhibits possessing any particular historical interest; we pass, therefore, to the display of those things which may be taken to illustrate the rapidly increasing requirements of modern medicine, towards the advance of which mechanical skill and the enormous progress which pharmacy of late years has made, contribute not a little. For this purpose we may classify the exhibits under the following heads: (1) Drugs and their various administrative forms; (2) Medical and Surgical Appliances; (3) Special Foods and Food Adjuncts; (4) Sanitary Appliances; (5) Mineral Waters, Beverages, &c.; (6) Miscellaneous; and (7) Literature.

I.—DRUGS.

Notable progress has been made in the preparation of the organic remedies of animal origin, and it is to be observed with considerable satisfaction how fully alive the bulk of manufacturing chemists are to the importance of organic extracts being of a standard and thoroughly reliable order. Messrs. Burroughs, Wellcome and Co. (of Show-hill, E.C.), for instance, have been remarkably successful in providing a permanent substitute for the aqueous alcoholic and glycerine extracts. Thus tabloids representing the whole substance of the organ from which they are prepared, so insuring the presence of the active principle, are now made embodying the extracts of thyroid gland, thymus gland, supra-renal substances, ovarian substance, didymin (orchitic substance), cerebrinin, pituitary body, kidney substance, spleen substance, uterine wall substance, bone medulla, and pineal gland. A dry variety of anti-diphtheritic serum, in the form of brilliant non-deliquescent scales, is also supplied. Messrs. Allen and Hanburys (of Plough-court, Lombard-street, E.C.) make also reliable preparations of animal extracts, notably thyroidin in the form of powder to be administered as cachet, or tablet, or as a liquid in their elixir. Typical of these are the grey matter of the brain, bone marrow extract, thymus gland extract, and so on, while this firm have also in hand the disposal of the antitoxins prepared by the British Institute of Preventive Medicine. With the stamp of approval of experimental investigation upon them are the similar preparations of Messrs. Willows, Francis, and Butler (of 100, High Holborn), who have given special attention to this important line of manufacture, extractum corticis cerebri, supra-renal preparations, pituitary body, thyroid extract, pancreatic extract, orchitic extract, being amongst the new therapeutic agencies of this class which they prepare. Evidence again of the necessity which large druggists have found of adding a bacteriological laboratory to their equipments is afforded in the anti-diphtheritic serum of Messrs. Parke, Davis and Co. (of North Audley-street, W.), the strength of which is determined by Behring's method, while every precaution known to science is taken to insure its sterility. Pure sterilised culture media are also supplied by this firm. Desiccated thyroids—one gland equals twelve grains—prepared from fresh healthy glands, carefully dried and freed from grease, are supplied, too, by Messrs. Armour and Co. (of Chicago), the excellence of whose laboratory products is well-known. The extract is procurable in the convenient form of tablets of five grains, each being equivalent to one-third of an entire healthy gland. The ingenious palatinoids of Messrs. Oppenheimer and Co. (of Worship-street, E.) afford again not only an excellent means of administering the organic extracts, but also of preserving them from change. Thus enclosed in the tiny, watch-glass, air-tight jujube are to be found thyroid, thymus, supra-renal, red bone medulla, and pituitary body substances. Organic extracts were also amongst the very long list of preparations shown by Messrs. Ferris and Co. (of Bristol). Every possible care is taken to make them reliable since each gland is minutely examined before being used, and all diseased lobes are rejected while every appliance used during the process is kept jealously sterilised.

Coming to those drugs which, in contrast to the remedies just described, are of chemical and botanical origin, we may first notice the various and multifarious administrative forms in which they are now fashioned and with a distinctive form of which so many firms are identified. Messrs. Burroughs, Wellcome & Co., for example, have placed at the practitioners' disposal almost every known remedy in the form of tabloid. Amongst the recently added we may mention the Blaud's pill tabloid, aural tabloids, nasal tabloids, tea tabloids, photographic tabloids, soloids (tabloids of mercuric chloride convenient for preparing an antiseptic mercurial solution of the strength recommended by the Local Government Board Memorandum of 1892). Under the name of tabellæ Messrs. Allen and Hanburys possess a list well-nigh replete with the remedies of the Pharmacopœia. Amongst those which call for special mention are those containing bitter medicines, coated with sugar, as cascara, quinine, &c. Other tabellæ are made, which, consisting of sparingly soluble substances, like bismuth, sulphonal, &c., are so prepared as to readily disintegrate on coming in contact with moisture. Hypodermas or tabellæ, which dissolve instantly without the aid of either heat or trituration, are admirably adapted for the ready and rapid preparation of a solution for hypodermic purposes. Convenience and ease of administration of drugs in loose powdered form are again exemplified in the palatinoid of Messrs. Oppenheimer, while there are obvious advantages in the ingenious bipalatinoid, in which two drugs may be kept apart until they are administered, when the ingredients react, producing the new and freshly obtained medicament, as for instance, carbonate of iron from carbonate of soda and sulphate of iron (Blaud's formula), arseniate of iron from arseniate of soda, and sulphate of iron and so on. Novelties of administrative form are illustrated again in the admirable gelatine lamels of Messrs. Savory and Moore (of New Bond-street) which consist of small gelatine sheets ruled in squares and impregnated with the required medicament, each square containing a definite quantity. Thus the quinine sulphate lamel contains one grain of the drug in each square. Worthy of special mention also are the elegant preparations of the same firm—gelatine ophthalmic discs. First prepared by Messrs. Savory and Moore, these convenient and absolutely clean means of applying drugs for ophthalmic purposes have come into extensive use. They consist of delicate films of soft gelatine impregnated with a perfectly definite weight of the medicament. Accuracy of dosage, constancy and reliability of composition, are the advantages secured by the method of Messrs. Duncan, Flockhart & Co. (of Edinburgh), which is illustrated in their capsules, cachets, and permanently plastic pills. The Blaud capsules, for example, never harden, and contain 92 per cent. of iron in the ferrous condition. The Morstadt cachet shown by Messrs. Thomas Christy and Co. (of Lime-street, E.C.) is another well-known means of exhibiting medicaments, and consists of sunk discs of rice paper. A very large and excellent variety of preparations in capsules, tablets, sugar-coated pink granules, ophthalmic and hypodermic tablets, tablet triturates were amongst the

Digitized by Google

brilliant show of Messrs. Parke, Davis and Co. The "triturates" containing the finest materials, are claimed to be permanent, soluble, and therapeutically efficient. No less than eighty varieties of medicinal capsules of soluble gelatine occur in the well-stocked list of Messrs. Ferris and Co. (of Bristol), who also prepare soluble pearl- and gelatine-coated pills, as well as tablets of compressed drugs. Messrs. Cooper and Co. (of Gloucester-road, South Kensington) have recently introduced a novel and important departure in cachets. Thus delicately coloured cachets are prepared, or white cachets upon which is printed a neat inscription indicating the nature and quantity of the contents. The printing is executed either upon the ordinary white cachets or upon those of which the paste is previously tinted the desired colour. The colours employed are perfectly harmless, and comprise pale or dark rose, carmine, garnet, sky blue, pale salmon, &c. The process is elegant and the product the perfection of cachets. The pills and pastils, and especially the latter, afford additional evidence of the elegance and superiority of the specialities and administrative forms of drugs shown by this firm. A large variety of capsules of desirable flexibility and solubility, including Blaud's pill, salol, guaiacol, cascara, and other drugs, were amongst the improved pharmaceutical preparations of Messrs. C. J. Hewlett and Son (of Charlotte-street, E.C.). Capsules of creolin for internal use were exhibited by Jeyes' Sanitary Compounds Company (of Cannon-street, E.C.). Every kind of convenient administrative means of exhibiting drugs were comprised in the productions of Messrs. Robertson and Co. (of Edinburgh) amongst those calling for special notice being the excellent flexible gelatine ferruginous capsule, the elegant "gelatine perles" of apiol, calcic sulphide, &c., capsules for export, glyco-gelatine pastils of various combinations, and compressed drugs. Specialities of the same class occurred also in the exhibit of admirably designed, soluble, transparent, capsuled, pearl-coated, and sugar-coated pills and granules of Messrs. Mackey, Mackey and Co. (of Grange-road, Bermondsey, S.E.). Several of the excellent pharmaceutical preparations of Mr. W. Martindale (of New Cavendish-street, W.) consisted of pastils, pilules, and granules, capsules, gelatinous medicated chocolate, and other forms calculated to afford ease and convenience of administration, while with the same aims in view were the cachets, compressed pellets, tincture pellets, pearl-coated pills and pilules, oval gelatine pills, and the flexible and soluble gelatine capsules comprising the excellent specimens of pharmaceutical elegance and skill of Messrs. Wyleys & Co. (of Coventry and Birmingham). Lastly the tablets, parvules, and granules of Messrs. F. Newbery and Sons (of King Edward-street, E.C.) including preparations of ingluvin, the digestive substance of the gizzard of the chicken, which has the remarkable property of arresting certain kinds of vomiting (notably that of pregnancy), demand attention.

We may next review the new remedies and the various improvements connected with the preparation of drugs which came before our notice. Several were to be observed claiming special features, or some novelty or improvement in regard to such important points as therapeutic activity, certainty of action, and so forth. In this connexion the step recently taken by Messrs. Duncan, Flockhart & Co. of supplying chloroform containing about 1 per cent. of alcohol is one of the first importance, since, as they state, while this addition has no effect in diminishing its anæsthetic power, it renders the chloroform practically non-decomposable under any circumstances. The specific gravity of the new product becomes thus reduced to 1,490, a fact which should be borne in mind when chloroform is ordered from the firm. Amongst the new and recent remedies supplied by Messrs. Allen & Hanburys are acidum boricum, which in doses of 10 to 15 grains is said to be of use in typhoid fever, and may be given with antifebrin, quinine, naphthalin, or salol; acidum lacticum is of benefit in diarrhœa, half a tumblerful of a 2 per cent. solution to be taken twice daily; agathin, a salicyl-methyl-phenylhydrazine in the form of pale greenish laminæ free from taste and smell, which possesses marked antineuralgic properties, for which it is administered in half-grain doses; analgen for neuralgia is tasteless and as much as forty-five grains may be given in the twenty-four hours; benzene, pure or mixed with lard, offers a successful means of treating scabies, especially, it is said, when complicated with eczema; byno-cascara, a palatable and active preparation of cascara sagrada combined with malt extract, which by its diastatic action on starch foods tends to act as a laxative; cactus grandiflora, useful in functional disorders of the heart, especially in the distressing palpitation arising from reflex irritation in dyspepsia and in "tobacco heart"; chloralose, a compound of chloral and glucose, is serviceable in insomnia due to overwork or over-excitement, but is not of much use where sleeplessness is due to pain; it is conveniently given in cachets.

(To be continued.)

Medical News.

UNIVERSITY OF GLASGOW.—The following candidates had the degrees named below conferred on them on July 25th:—

DOCTORS OF MEDICINE (M.D.).

I. WITH HONOURS.

Monro, Thomas Kirkpatrick, M.A., M.B., C.M., Scotland.

II. WITH COMMENDATION.

Banks, Chas., M.B., C.M., Scotland.
Bell, Andrew Lees, M.B., C.M., Scotland.
Campbell, Finlay Stewart, M.B., C.M., Scotland.
Charles, John, M.B., C.M., Scotland.
M'Gregor, John, M.B., C.M., Scotland.

III. ORDINARY DEGREE.

Gardiner, P., M.B., C.M., Scotland.
Hay, Archibald Gilchrist, M.A., M.B., C.M., Scotland.
Macklin, Thomas Thornton, M.B., Scotland.
Macphail, James Merry, M.A., M.B., C.M., England.
Robb, James Jenkins, M.B., C.M., Scotland.
Smith, James, M.B., C.M., Scotland.
Wilson, James Allan, M.B., C.M., Scotland.

BACHELORS OF MEDICINE AND MASTERS IN SURGERY (M.B., C.M.).

I. HONOURS.

*Ferguson, Joshua, M.A., Scotland.
Pattullo, Henry Alexander, Scotland.
Walker, Ernest Alex., M.A., Scotland.

* Mr. Ferguson gains the Brunton Memorial Prize of £10, awarded to the most distinguished graduate in medicine of the year.

II. HIGH COMMENDATION.

Scobie, William, B.D., Scotland.
Stewart, Alexander Hamilton, Scotland.
Watson, Henry Allan, M.A., Scotland.
Howie, Robert, Scotland.
Lang, William Henry, B.Sc., England.
Young, Archibald, B.Sc., Scotland.

III. COMMENDATION.

Barr, Robert Brownlee, Scotland.
Stevenson, Alexander, Scotland.
Cowan, Samuel Donaldson, M.A., Scotland.
Lawson, William, Scotland.
Macrae, Farquhar, Scotland.
Fraser, Robert Mackechnie, M.A., Scotland.
Stuart, Emmeline Marie, Scotland.
Miller, Robert King, Scotland.
Watson, Malcolm, Scotland.
Anderson, John Lindsay, Scotland.
Muir, Adam Cubie, Scotland.
Bell, Thomas, Scotland.
Cormick, Frederick Burdett, Scotland.
Mowat, George, Scotland.
Miller, William Duncan, Scotland.
Alexander, William, Scotland.
M'Cash, James, Scotland.

IV. ORDINARY DEGREES.

Abbott, John Carson, U.S., America.
Adam, James, Scotland.
Allan, William, Scotland.
Anderson, Arthur Roland, Newfoundland.
Anderson, John, Scotland.
Anderson, John James Stevenson, Ireland.
Armstrong, Thomas, Scotland.
Baird, William Stephen, New Zealand.
Barker, Francis James, M.A., Scotland.
Blair, Alexander, Scotland.
Bödeker, Henry Albert, Burmah.
Burns, William, Scotland.
Campbell, Thompson, Scotland.
Chang, Vivian Ernest, China.
Clow, William, M.A., B.Sc., Scotland.
Cumming, John, Scotland.
Davies, Henry, Wales.
Divine, John, Scotland.
Donaldson, William, Scotland.
Dunning, Matthew, Scotland.
Edwards, Richard John, Wales.
English, Samuel, Ireland.
Findlay, James, Scotland.
Findlay, William David, Scotland.
Finkelstein, Albert Alfred, Russia.
Forrest, James Liddell, Scotland.
Forster, James, England.
Foulds, James Reid, Scotland.
Galloway, Andrew Fleming, Scotland.
Garrett, Thomas Cleator, Isle of Man.
Gillan, John, M.A., Scotland.
Graham, Walter, Scotland.
Grove, William, Scotland.
Hay, William, B.D., Scotland.
Holt, Arthur, England.
Hughes, Albert Barnes, England.
Jack, James, Scotland.
Jackson, John William, Scotland.
Jubb, George, Scotland.
Kerr, David, England.
Kerr, William James, Scotland.
Kirkhope, David Connor, Scotland.
Kirkwood, John, Scotland.
Lewis, David, Wales.
Louttit, John Dunlop, Scotland.
Mulholland, James Andrew Dixon, Ireland.
Munro, Donald, Scotland.
M'Coll, Daniel, Scotland.
M'Cormick, William Milligan, Scotland.
M'Donald, Duncan, Scotland.
Mackinnon, William Jones, Scotland.
MacLachlan, Lewis, Scotland.
M'Laren, Hugh, Scotland.
MacLay, Moses Neil, Scotland.
Macleod, William, Scotland.
M'Pherson, George, M.A., Scotland.
Oliver, Archibald Russell, Scotland.
Primrose, Edward James, M.A., Scotland.
Rae, John Broadfoot, Scotland.
Rankin, John, Ireland.
Robertson, John Neil, Scotland.
Sandilands, James, Scotland.
Smith, James, Scotland.
Sproull, James, Scotland.
Stevenson, Hugh, Scotland.
Stewart, Alexander, Scotland.
Stewart, James, Scotland.
Stirling, James, Scotland.
Thomson, Hugh Wright, Scotland.
Toland, Charles Kirk, Ireland.
Wolverson, Frederick, England.

VICTORIA UNIVERSITY.—The following candidates passed in the Final Examination of the Faculty of Medicine in July last:—

Part I.: G. Ashton, Owens; W. S. Badger, University; F. J. Batten, R. Bleasdale, H. M. Brown, A. H. Burgess. J. B. Clarke, H. Coates, and C. Coventry, Owens; H. M. Crake, University; P. H. Fearnsides, Yorkshire; H. Hamer, E. Hutton, W. F. Jackson, K. H. Jones, and A. T. Lakin, Owens; J. G. Martin, University; E. Monks, N. Neild, W. H. S. Nickerson, A. E. Normington, and J. S. Ross, Owens; S. T. Rowling, Yorkshire; E. A. Smith, University; L. Tong, Owens; A. A. Wood, University; and J. Wood, H. B. Woodcock, and H. C. Woodhouse, Owens.

Part II.: A. V. Davies, U. L. Desai, A. Greenwood, R. S. Hardman, and F. B. G. Holmes, Owens; C. E. Ligertwood, Yorkshire; J. P. Lowe, A. McDougall, J. T. Marsden, T. H. Miller, F. C. Moore, and J. H. Renshaw, Owens; J. V. Shaw and R. H. Trotter, Yorkshire; and B. V. Watkins, Owens.

The following were awarded Honours:—Class I. C. E. Ligertwood, Yorkshire; and F. C. Moore, Owens. Class II. R. S. Hardman, F. B. G. Holmes, T. H. Miller, and J. H. Renshaw, Owens; J. V. Shaw and R. H. Trotter, Yorkshire; and B. V. Watkins, Owens.

The Diploma in Sanitary Science was awarded to M. Parkinson and F. W. Sydenham.

BRITISH INSTITUTE OF PUBLIC HEALTH.—The annual dinner of the British Institute of Public Health was held on Wednesday, the 31st ult., at the Holborn Restaurant. Professor W. R. Smith was in the chair, and the company included Lord Playfair, the Japanese Minister, Sir Douglas Galton, Archdeacon Sinclair, and Sir George Kekewich.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.—The summer general meeting of the above association was held at King's College on Wednesday July 31. The chair was occupied by Dr. H. H. Phillips, Conn. (President). The attendance was a very large one, including Sir Thomas Crawford, K.C.B. (Chairman of Council), Dr. William Thomson, Vice President of the Royal College of Surgeons, Ireland, Surgeon-Major Ulick J. Bourke, Dr. Abraham, Dr. A. H. Benson (Dublin), Dr. J. Davison (Bournemouth), Dr. R. Fegan, (Blackheath), Dr. E. D. Mapother, Mr. R. O'Callaghan, Dr. S. A. K. Strahan, Mr. G. Stoker, Dr. W. H. White, and the Honorary Provincial Secretary (Mr. J. Stewart, F.R.C.P. Edin.), besides several visitors. The Hon. Provincial Secretary having given a *résumé* of the past action of the Council in reference to disabilities of Irish diplomates in connexion with honorary appointments in English public hospitals, Dr. Thomson moved, Dr. Abraham seconded, and it was carried unanimously, that a further effort be made on the first opportunity to reduce the number of English public hospitals in which honorary appointments on the staff are restricted to those holding English diplomas. Dr. Arthur H. Benson moved, Mr. Robert O'Callaghan seconded, and it was carried unanimously, that a special fund (to be called the "Hospital Appointments Fund") be raised forthwith to cover expenses connected with the abolition of hospital monopolies. To this fund a sum of nearly £50 was subscribed by those present at the meeting, which was thereupon adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BOWKETT, W. D., M.R.C.S. Eng., has been appointed Surgeon to the Winton Hospital, Queensland, vice Wellford.

BURNS, THOMAS, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Superintendent of the Lunatic Asylum at Porirua, near Wellington, New Zealand.

CLARIDGE, H. A. H., M.B., B.S. Durh., has been appointed Medical Officer for the Norton Canes Sanitary District of the Cannock Union.

COLYER, ARTHUR R., M.R.C.S., L.R.C.P., L.D.S., has been appointed Assistant Dental Surgeon to the Dental Hospital of London.

CROOM, J. H., M.D., C.M., F.R.C.P., F.R.C.S. Edin., has been appointed Physician to the Edinburgh Royal Maternity and Simpson Hospital.

DATE, W. H., M.R.C.S., has been appointed Medical Officer of Health for the Culmstock Rural Sanitary District, vice Randolph.

DOUGHTY, WM., L.R.C.P., L.R.C.S., L.M. Edin., has been appointed Medical Officer of Health for the Chillington Sanitary District of the Kingsbridge Union.

DYER, BERNARD, has been appointed Analyst for the County of Rutland, vice Emmerson, deceased.

EATON, JOSEPH, L.R.C.P. Irel., L.R.C.S., L.M., has been appointed Government Medical Officer and Vaccinator for the district of Hylston, New South Wales.

FENTON, JAS. L., M.B., C.M. Edin., has been appointed Health Officer for the Omeo Shire, Victoria, Australia.

FOOKS, E. E., M.B. Univ. New Zeal., has been appointed Medical Superintendent of the Lunatic Asylum at Wellington, New Zealand.

FOX, WALTER, M.B., C.M. Glasg., has been appointed Government Medical Officer and Vaccinator for the district of Narandera, New South Wales.

GARDE, H. C., L.K.Q.C.P. Irel., L.R.C.P., L.R.C.S. Edin., has been appointed City Health Officer, Queensland.

HEARDER, FREDERIC P., M.B., C.M. Edin., has been appointed Second Assistant Medical Officer to the West Riding Asylum, Wakefield, vice Mr. Craig, resigned.

HEATHCOTE, H. C., M.B., Ch.B. Vict. (Owens College), has been appointed Medical Officer and Public Vaccinator for the Tiverton Sanitary District.

HOETS, A. K., M.R.C.S. Eng., has been appointed Government Medical Officer and Vaccinator for the district of Burrowa, New South Wales.

HOGG, C. A., M.B., M.S. Edin., has been appointed House Surgeon to the Launceston Hospital, Tasmania.

HOLMES, L. S., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Health Officer for the Port of Launceston, Tasmania.

HINDER, H. V. C., M.B., Ch.M. Syd., has been appointed Honorary Assistant Surgeon at the Prince Alfred Hospital, Sydney, New South Wales.

HUNTER, DAVID, has been appointed Fourth Assistant Medical Officer to the West Riding Asylum, Wakefield, vice F. O. Simpson, promoted.

JAMES, D. P., M.R.C.S. Eng., F.R.C.S., L.R.C.P. Lond., has been appointed Health Officer for the Port of Wellington, New Zealand.

JERMYN, FRED. D., M.B., Ch.B. Melb., has been appointed a Public Vaccinator in South Australia.

KEITH, ARTHUR, M.D. Aberd., M.S., F.R.C.S. Eng., has been appointed Senior Demonstrator of Anatomy at the London Hospital Medical School.

LYLE, H. WILLOUGHBY, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Lecturer in Animal Biology and Demonstrator of Physiology at King's College, London, vice Brodie, resigned.

MACBIRNIE, STUART, M.B., Ch.M. Glasg., has been appointed Medical Officer to the Coal Creek Miners at Korumburra, Victoria, Australia.

MACKAY, J. S., M.D. St. And., D.P.H. Edin., has been appointed Medical Officer for Kirkcaldy.

MACHATTIE, T. A., M.B., Ch.M. Edin., has been appointed by the Railway Commissioners Local Railway Medical Officer for the Bathurst District, New South Wales.

MACKINTOSH, ARTHUR, M.B., C.M. Edin., has been appointed House Surgeon to the Northern Infirmary, Inverness, vice Williamson, resigned.

NEALE, A. J., M.D., Ch.M. Edin., has been appointed a Public Vaccinator for the District of Palmerston, North, New Zealand.

PALMER, M. H. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District of the Newbury Union.

PATTESON, R. GLASGOW, M.B., B.Ch. Dub., F.R.C.S. Irel., has been appointed Surgeon to the Meath Hospital and County Dublin Infirmary, vice Sir G. H. Porter, Bart., deceased.

REILLY, F. B., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Billinge Urban Sanitary District, vice Molyneux, deceased.

ROBERTS, F. H., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health for the Llandrindod Wells Urban Sanitary District.

ROWLANDS, GEO. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Government Medical Officer and Vaccinator for the District of Narromine, New South Wales.

TAYLOR, J. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Methley Urban Sanitary District, vice Wigan.

SIMPSON, FRANCIS O., L.R.C.P., M.R.C.S., has been appointed Pathologist and Third Assistant Medical Officer to the West Riding Asylum, Wakefield, vice W. le Andriezen, resigned.

ROOCROFT, W. MITCHELL, M.R.C.S., L.R.C.P., has been appointed Consulting Surgeon to the Lancashire and Cheshire Nurses' Permanent Relief Society, vice Bamish, deceased.

VOELCKER, ARTHUR F., M.R.C.P., M.D. Lond., M.R.C.S., has been appointed Assistant Physician to the Middlesex Hospital.

WAKELAM, E., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health for the Springhead Urban Sanitary District, vice Andrew, resigned.

WATSON, A. H. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator at Port Broughton, South Australia.

WEEKES, F. H., M.R.C.S., has been appointed Fifth Honorary Medical Officer of the York Dispensary.

WILKINS, JOHN, F.R.C.S. Edin., M.R.C.S. Eng., has been appointed a Surgeon to the Permanent Militia at Auckland, New Zealand.

WILLS, C., M.R.C.S., has been appointed Medical Officer by the District Council for Blyth and Cuckney.

WILSON, THOMAS, M.D. Lond., B.S., F.R.C.S., has been appointed Honorary Medical Officer of the Birmingham Lying-in Charity.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CHARING-CROSS HOSPITAL MEDICAL SCHOOL, 62, Chandos-street, W.C.—Lectureship on Physiology. A minimum of £300 a year is guaranteed for the teaching of physiology, in addition to a grant for working expenses.

CONVALESCENT FEVER HOSPITAL, Gore Farm, Darenth, Kent.—Dispenser. Salary, £5 a month, with board, lodging, and washing. Applications to the Medical Superintendent at the hospital.

STOKE NEWINGTON, CLAPTON, WEST HACKNEY, AND DALSTON DISPENSARY, 106, High-street, Stoke Newington, N.—Resident Assistant House Surgeon. Salary £50 per annum, with board and lodging.

Births, Marriages, and Deaths.

BIRTHS.

ALCOCK.—On July 21st, the wife of Richard Alcock, M.D., Burlington-crescent, Goole, of a daughter.

ANDREWS.—On July 25th, at R.N. Hospital, Haslar, the wife of Surgeon O. W. Andrews, Royal Navy, of St. Briavel's, Glos., of a daughter.

BLUCKE.—On July 24th, at Rowberry, Donhead, St. Andrew, the wife of Fredk. H. S. Blucke, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

FLINT.—On July 30th, at Westgate-on-Sea, the wife of Arthur Flint, M.D. Brux., L.R.C.P. Lond., M.R.C.S., J.P., of a daughter.

HEATH.—On July 28th, at Cavendish-place, Cavendish-square, W., the wife of Charles Heath, F.R.C.S., of a son; who survived his birth only a few hours.

HEYWOOD.—On July 24th, at Lower Bank, Darwen, the wife of T. W. Heywood, L.K.Q.C.P. Irel., M.R.C.S., of a son.

JONES.—On July 22nd, at Stokesley, Yorks., R.S.O., the wife of Arthur Jones, M.R.C.S. Eng., L.R.C.P., of a son.

MACEVOY.—On July 24th, at 41, Buckley-road, Brondesbury, London, N.W., the wife of H. J. Macevoy, M.D., B.Sc. Lond., of a daughter.

MAPLESON.—On July 28th, at Nottingham-place, W., the wife of Horsley Mapleson, M.R.C.S. Eng., of a son.

MOORE.—On July 9th, at Story-hill, St. Andrew, Jamaica, the wife of York Moore, L.R.C.P. Edin., M.R.C.S., of a son.

RUSSELL.—On July 23rd, at Queen Anne-street, W., the wife of John Ronaldson Russell, M.R.C.S., L.R.C.P., of Quebec House, Westerham, Kent, of a daughter (prematurely).

MARRIAGES.

ANGEL-MONEY—DOWDELL.—On June 12th, at St. John's, Darlinghurst, Sydney, N.S.W., Angel-Money, M.D. Lond., F.R.C.P. Lond., of Hunter-street, Sydney, to Amy Mona, daughter of the late Charles Dowdell, Esq., of Hawthorn, Victoria.

HAKE—BALDWIN.—On July 25th, at St. Mary the Virgin, Prittlewell, James Hake, M.R.C.S. Eng., L.R.C.P. Lond., to Rose, second daughter of James William Baldwin, of West Cliff, Southend.

MARCH—MANNING.—On July 27th, at Laverstock Church, near Salisbury, Joseph Ogdin March, M.R.C.S., L.R.C.P. of St. John's House, Lechlade, Gloucestershire, to Grace Ellen, eldest daughter of Henry John Manning, of Laverstock, near Salisbury.

PRESTON—BARRY.—On July 25th, at St. John's Church, Ryde, I.W., Lionel Litchfield Preston, M.B. and B.S. Durh., fourth son of Alfred Preston, of Elsworthy-road, London, N.W., to Evelyn, only surviving daughter of Major R. Edwyn Barry, late 29th Regiment, of Lindenhurst, St. John's-park, Ryde, I.W.

SPEECHLY—BARRETT.—On Tuesday, July 30th, in the Parish Church, Neston, Cheshire, by the Rev. A. W. Humphreys, assisted by Canon Turner, the vicar, Harry Martindale Speechly, M.R.C.S. Eng., L.R.C.P. Lond., of Parkgate, Cheshire, eldest son of the Right Rev. Bishop Speechly, to Mary Barrett, B.A. Viet. Univ., eldest daughter of the late Rev. W. F. Barrett, formerly headmaster of Mostyn House School and senior curate of Neston.

DEATHS.

BOTT.—On July 28th, Camilla, beloved wife of W. Gibson Bott, J.P., L.R.C.P., &c., at 414, Clapham-road, S.W., aged 43 years.

BRUMWELL.—On July 26th, at 136, Duke-street, Southport, James Teasdale Brumwell, M.R.C.S. Eng., L.S.A., aged 78 years.

JAMIESON.—On July 26th, at Shanghai, China, R. A. Jamieson, M.D. Irel., M.R.C.P. Lond., M.R.C.S., aged 53 years.

LEWINS.—On July 22nd, at Nottingham-place, W., Staff-Surgeon-Major Robert Lewins, M.D. Heidelberg.

LEY.—On June 10th, 1895, at the Universities' Mission, Central Africa, in his 37th year, Herbert Ley, M.R.C.S. Eng., eldest son of the late William Ley, of Westbourne-terrace, London, W.

MARSHALL.—On July 25th, at his residence, Liverpool-street, Dover, John Marshall, L.R.C.P. Lond., M.R.C.S., J.P., aged 64 years.

NEALE.—On July 21st, three weeks before the completion of her 103rd year, Caroline Elizabeth Neale, mother of Richard Neale, M.D. Lond.

PARKER.—On July 30th, on his 60th birthday, Robert Parker, M.R.C.S., Malpas.

TOMES.—On July 29th, at Upwood Gorse, Caterham, Sir John Tomes, F.R.S., F.R.C.S., aged 80 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

RISK OF OPERATING WITHOUT CONSENT.

AN action involving a claim for £2000 has been tried in Belgium which is of considerable interest to surgeons. It appears that a lady who suffered from uterine hæmorrhage was recommended by a consultant who was called in by her family attendant to allow the uterus to be curetted, to which she and her husband consented. When the operation was begun it was discovered that there was cancer of the uterus, and the operator and the family practitioner decided then and there to remove the whole organ, the result being that the patient died from hæmorrhage. As neither the patient nor the husband was consulted about the hysterectomy it was held by the court to be unjustifiable. The damages were, however, reduced to £200.

Divining Rod.—We have been unable to find any recent article referring to the supposed efficacy of the hazel switch in our columns.

W. S. S.—The letter was duly received.

"THE LOSS OF SIGHT, HEARING, AND SPEECH."

To the Editors of THE LANCET.

SIRS,—The following particulars relating to an answer given in THE LANCET, April 6th, 1895, reaches you perhaps too late to be of any use to Mr. T. R. L. Edwards.

I remember in 1872, in visiting the Hospital for the Blind at Lausanne, that they showed me a girl fourteen years old who was born deaf, and who at a very early age had lost her eyesight in consequence of an attack of small-pox. Notwithstanding this she could learn to articulate sufficiently distinctly many words, with the patient exertions of speaking of the teacher while the child was holding her hands applied to the larynx of the speaker. They also told me of other instances of the deaf and blind being taught to speak, and particularly of the case of one patient, deaf and blind from birth, who had at that time left the institute, and had succeeded in becoming a very able turner—so able as to have executed by himself a fine shelf, which was shown to me. I do not remember the name of the then old director of the institution, but the oculist at that time was Dr. Marc Dufour, a pupil of Horner.

I am, Sirs, very truly yours,

Pisa, July 15th, 1895. DR. P. SONSINO.

Digitized by Google

"ALLEGED TOUTING BY A PUBLIC VACCINATOR."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 27th Dr. J. Lumsden Bell accuses me of having been vindictive with regard to his assistant, Dr. Slane, and desires you to take Dr. Slane out of the pillory in which, he states, I have been the unfair means of placing him, and to put me there in Dr. Slane's stead. I ask you, in fairness to myself, to permit me to explain my position once more. I distinctly deny any vindictive feeling in this matter. I have suffered annoyance by the acts of Dr. Slane, and have been indignant at his obtruding himself upon my patients in such a manner that many have complained to me of his visits.

Following Dr. Bell's example, I will ask you one "straight question" for my guidance in the future. Am I justified in having complained of Dr. Slane visiting my patients—patients who are not in any sense of the word defaulters (*vide* Dr. Bell's letter in THE LANCET of July 27th); and shall I be justified in looking upon any future act of this sort as one of touting? The whole matter is in that question. Dr. Bell, referring to your comments on my letter found in THE LANCET of May 18th, wrote to me the following statement: "The conduct denounced by yourself and the Editors of THE LANCET is equally abhorrent to Dr. Slane and myself." I take it that by this Dr. Bell and Dr. Slane are willing to stand or fall by your verdict. Certainly that is my determination. Either Dr. Slane, as public vaccinator, has the right of *entrée* to another medical man's patients, or he has not. If you decide that he has, then I will willingly occupy the pillory which Dr. J. Lumsden Bell, by casting aside the *nom-de-plume* over which I wrote my letters to you and placing in its stead the full names of all concerned, has prepared. I am, Sirs, yours faithfully,

Nafferton, Yorks, July 30th, 1895. CHARLES H. ECCLES.

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—Will you allow me one word in reply to "R. B. F."? I think he forgets the effect of custom. To talk of "Solicitor A.," or to address a dentist as "Dentist," would be startling because novel. But to speak of a physician as "Dr. B." and to address him as "Doctor" is justified by very old-established custom. I do not see that the substitution of a synonym proves anything more than that the claim of the diplomate to the title rests upon the courtesy accorded to him as a member of the medical profession. My error concerning the claim of the L.S.A. put aside, no other claim than that of courtesy has been advanced. To take a rather similar case. Would "R. B. F." address the commander of an ocean liner as "Master of a trading vessel" because, though a captain in the ordinary interpretation of the word, he does not hold the Queen's commission? If the title "Dr." were strictly restricted to those who alone can legally claim it—namely, holders of a Doctor's degree—the position would be logical and defensible. And however much we might protest against the inequality of these degrees, and the unfairness of refusing to the great majority of the profession all opportunity of obtaining them, we should not be able to question the justice of the restriction itself. But if the title is to be given by courtesy to certain men who do not hold the M.D. degree, why is it not to be given by courtesy to all medical men, or at least, in accordance with old-established custom, to all physicians? The distinction implies a slur upon the diplomate which is not justified by the comparative value of his qualifications. I am, Sirs, yours faithfully,

July 23rd, 1895. NOT L.S.A.

To the Editors of THE LANCET.

SIRS,—The above subject is so simple that I am not a little surprised to find members of our profession raising a discussion about it. The whole thing lies in a nutshell, which a layman, "R. B. F.," in THE LANCET of July 20th, has efficiently cracked and settled once for all. With your permission, however, I should like to make a few additional observations. The title of Doctor is the only prefix title in the medical profession (to which the possessor of a Doctorate alone has a right), and is the highest academical honour which a University can bestow upon its graduates, and in doing so acts as the mouth-piece of the Crown. This title is, therefore, in kind if not in degree, equal to any other prefix title, and neither the University which granted it nor the General Medical Council can deprive its possessor of it. A special Act of Parliament alone can do so. Under certain circumstances they can remove his name from the Medical Register, but can do nothing more. As Universities alone are empowered to confer this title it is evident that no merely licensing bodies can do so. Any one, therefore, not possessed of a Doctorate and assuming its prefix title makes himself not a little ridiculous.

I am, Sirs, yours truly,

July 24th, 1895. M.D. EDIN.

To the Editors of THE LANCET.

SIRS,—Allow me to get the opinion of the profession through your valuable columns anent the following scheme:—Let the universities remove the stumbling-block of "residence" in the case of a Licentiate of five years' standing, so that thereby he may compete for the M.B. and subsequently the M.D. I need hardly say that it is a great hardship on a Licentiate to wait until he is forty years old and fifteen years qualified before proceeding for the M.D.

I do not think that it is right for some members of the profession to limit the title of "Dr." to M.D.'s, because the very title itself has become to mean a "medical man." I am, Sirs, yours truly,

July 22nd, 1895. A LICENTIATE.

THE BABY FASTENER.

THIS is a patented appliance for preventing infants up to three years of age from coming out of their cots or cribs. It consists of a very stout band of webbing, thirty inches long and five inches wide, which is placed on the undersheet, and secured by its attached tapes beneath either the mattress or the bed itself. Two linen flaps stitched to this band are buttoned over the child's body just below the armpits. They leave room enough for the child to turn itself round inside them, and when the child is to be taken out of the cot only three buttons require to be unfastened. With a view to cleanliness the baby fastener is made so as to be easily washed, all the materials being unshrinkable. The manufacturers are Messrs. John J. Wilson and Co., Kendal, Westmorland. They also make a modification of the same article for the use of adults suffering from delirium tremens.

Mr. Horsley Mapleson.—The name mentioned in the advertisement sent by our correspondent does not appear on the Medical Register, so that the General Council of Medical Education and Registration have no control over the advertiser.

Subscriber.—(1) We cannot answer as to the *legality* of the step without seeing the bond between our correspondent and the body in question. (2) It is usual to intimate that details will be given on demand.

L.R.C.P. Lond., M.R.C.S. Eng.—The choice between the prefix and the suffix is a matter of taste. Either is right.

"AN ADVERTISEMENT OF A HOSPITAL."

To the Editors of THE LANCET.

"ANYBODY in LONDON having spare time on Monday, 22nd, or Tuesday, 23rd July, is INVITED to VISIT the POPLAR HOSPITAL for ACCIDENTS between 2 and 7 o'clock.

Newly built. Newly fitted. No debt.
No horrors. No infection.
Best Way.—Drive or bicycle, 45 minutes from West-end.
Another Way.—Blackwall Omnibus from Piccadilly-circus, 75 minutes.
Another Way.—Train to Aldgate, thence by yellow tram."

SIRS,—I note that in your issue of July 27th you write that the above advertisement, for which I am solely responsible, is unfitting, undignified, savours too much of a "Cheap Jack," and is wanting in taste. Somewhat severe this—even for THE LANCET. You will, I am sure, forgive me if I do not dispute with you the question of good or bad taste. That must always be a matter of opinion. The reason I am "drawn" to make reply to your scolding—which is an idiotic thing to do—is because you write, "We do not think the above advertisement a very fitting one, inasmuch as it contains remarks that might tend to keep charitable visitors away from other hospitals." I confess this annoys me, because it implies that I had the intention of hurting other hospitals to the advantage of my own. Nothing was, or can possibly be, further from my intention. I fear, Sirs, your profession, entailing as it does the constant diagnosing for disease, has led you unconsciously to be too ready to imagine and discover evil where none exists. My advertisement was not addressed to "charitable" visitors. They visit hospitals now. It was addressed to the careless and curious, and my harmless sentences—as I thought them till you laid bare their wickedness and malignity—were in answer to the constant excuses I have made to me when I beg people to visit the hospital. "*Newly built*," "*newly fitted*," were the attractions I had to offer my visitors to induce them to take an hour's journey in a Blackwall 'bus or a yellow tram. "*No debt*" was to assure them that they would not be badgered to pay for those attractions. I wanted not to get their money—then—but to spread an interest in the hospital's welfare. "*No horrors*" was inserted to dispel an idea which in my less dignified and less isolated position in life I meet with constantly—that in an accident hospital rivers of blood flow about on the floor all day. And, lastly, "*No infection*" was added to induce fond mothers to bring their children, and so instil early into them some kindly thought for the suffering poor.

Come off your stilts, please, Mr. LANCET, and do a little more for our hospitals than merely reporting hospital practice and seeking and suggesting evil motives where none exist.

I am, Sirs, yours faithfully,

July 28th, 1895. SYDNEY HOLLAND.

*** We agree with the Hon. Sydney Holland that to argue about questions of taste is futile. Of the goodness of his motives or of his anxiety to promote the welfare of the institution of which he is chairman we have no shadow of doubt, but we cannot pretend to like the advertisement.—ED. L.

HONOURS TO THE PROFESSION: AN UNSOLICITED TESTIMONIAL.

To the Editors of THE LANCET.

SIRS,—While walking in a not very fashionable part of this neighbourhood the other day I noticed a young lady aged six or seven suddenly stop, clutch her companion, aged four or five, point at me and say, "That's the man what done my father better." After twenty-five years' service as a parish medical officer, surely, Sirs, I may feel that my labours have not been altogether in vain.

I am, Sirs, your obedient servant,

Crouch End, July 28th, 1895. F. ORTON, M.D.

Digitized by Google

"THE POST OF SURGEON ON THE CABLE TELEGRAPH SHIPS."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent "H.A.B." I beg to give the following particulars concerning these posts with the Silvertown Company's ships (the Indiarubber, Guttapercha, and Telegraph Co.).

The pay is £13 per mensem, 1*s.* a day wine allowance, full amount of cost of uniform, and as a rule a bonus of at least one month's pay at the end of the voyage. Aboard their largest ship, the *Silvertown*, will be found the most perfect surgery afloat. Drugs are ordered by the surgeon for the voyage at his discretion, and a complete set of surgical instruments and appliances provided. The surgeon, moreover, takes in this company's service his rightful position; he is a senior officer, and his words, on matters appertaining to his own work, are law. On the ships of the Telegraph Construction and Maintenance Company the pay is £12 per mensem, 1*s.* 6*d.* per day wine allowance, but no uniform allowance and no bonus. The surgeon here will not find himself in quite so good a position as in the service of the first-mentioned company; still, the appointment is a comfortable one. On *cable-laying* expeditions the length of voyage varies, of course, with the amount of cable to be laid, the distance abroad to be steamed to the starting point, and the difficulties of laying. No average time can be mentioned, each voyage having its own peculiarities. On cable-repairing ships, of which the Eastern Telegraph Company have several, and the Central and South American Cable Company two, the pay is about £15 per month, and the length of service three years.

Both the first-mentioned companies also repair cables, sending out special ships for the work. The pay on these expeditions is as mentioned under the several companies; the length of the voyage is always uncertain owing to the difficulties experienced in the work. The life is an exceedingly pleasant one, the object of the expedition is most interesting, and the ships are invariably comfortable to live in. As to professional work the men are a picked lot physically; the surgeon must be prepared, however, at any moment during the actual laying of the cable to perform serious operative work (single-handed as a rule), for should an accident occur, which happily is rare, it means a terrible one. Finally, if the surgeon has not yet "crossed the line," he must look forward to being introduced to Father Neptune and the ceremonies and penalties exacted from one who is not yet a "true son of Neptune." I shall be glad to see your correspondent personally, if he should wish it, and give him further information. Crouch, in "On a Surf-bound Coast" and in "Glimpses of Fever-land" (Allen and Co.), gives much chatty information on the subject of cable-laying.

I am, Sirs, yours faithfully,
H. ATHILL CRUTTWELL,
July 29th, 1895. Late Senior Surgeon, T.S. *Silvertown*.

Mr. F. Hone Moore.—It is impossible for us to say what the General Medical Council would do under the circumstances. There are probably some legal points involved quite outside medical ethics, with which points the Council might have no power to deal.

Enquirens. — The proceeding is certainly not illegal. If the word "medical" has been used in any way suggestive of the possession of medical qualifications, the General Medical Council might be informed.

C. M.—A communication involving such a grave charge must (and we are sure our correspondent will agree with us) be supported by names, dates, and the fullest details, *for our information only*.

"LORD BYRON'S LAMENESS."

To the Editors of THE LANCET.

SIRS,—In answer to the query of "M.B., C.M." in THE LANCET of July 20th I quote the following statement of Edward John Trelawney, in his "Records of Shelley and Byron":—

"To confirm or remove my doubts as to the exact cause of his [Byron's] lameness, I uncovered the Pilgrim's feet, and was answered—it was caused by the contraction of the back sinews, which the doctors call 'tendo Achillis,' that prevented his heels resting on the ground and compelled him to walk on the forepart of his feet; except this defect his feet were perfect. ..... It was generally thought his halting gait originated in some defect of the right foot or ankle; the right foot was most distorted, and it had been made worse in his boyhood by vain efforts to set it right. He told me that for several years he wore steel splints, which so wrenched the sinews and tendons of his leg that they increased his lameness; the foot was twisted inwards, only the edge touched the ground, and that leg was shorter than the other. His shoes were peculiar—very high-heeled, with soles uncommonly thick on the inside and pared thin on the outside; the toes were stuffed with cotton-wool, and his trousers were very large below the knee and strapped down so as to cover his feet. The peculiarity of his gait was now accounted for; he entered a room with a sort of run, then planted his best leg well forward, throwing back his body to keep his balance."

Byron, therefore, seems to have suffered from double talipes equinovarus, the deformity being greatest in the right foot. He was manifestly at fault in attributing his deformity to some act of over-delicacy on the part of his mother at her accouchement, as he says in one of his letters. Byron took no interest in medical knowledge, and appears to have disliked medical men as a class. I am, Sirs, faithfully yours,

Surbiton, July 22nd, 1895. R. H. REYNOLDS.

AN ECONOMICAL SOLICITOR.

To the Editors of THE LANCET.

SIRS,—I gave evidence in a sessions case recently. The solicitor for the prosecution sent me my fee of £1 1*s.*, less banker's commission and postage, 4*d.* I want to know whether he can legally do so, as I write and ask for the 4*d.*, and he declines to send it.

I am, Sirs, yours faithfully,
July 30th, 1895. C. G.

J. H. D.—A medical man's claim to attend a patient who sustains an accident does not lapse because he happens to be out of the way at the time. Any medical man knowing of his former relations to the patient should consider them and offer to hand the case over. If the patient or his parents insist on the practitioner called in continuing his attendance, he is scarcely at liberty to decline to do so. But all his influence should be exerted to restore the patient to his original attendant. There was in this case a want of firmness and promptness in the parent. We see no intention on the part of the practitioner called in (B) to act unprofessionally; but when he learnt that A was the family medical attendant he would have done well to offer to hand the case over before operation.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

During the week marked copies of the following newspapers have been received:— *Wellington Journal, Sussex Daily News, Free Russia, Brighton Argus, Western Daily Mercury, Sun, Manchester Guardian, Kidderminster Shuttle, Bombay Gazette, Walsall Observer, Liverpool Mercury, Sheffield Telegraph, Birmingham Post, Glasgow Evening News, East Anglian Daily Times, Newcastle Chronicle, Oldham Standard, Halifax Guardian, Times of India, Cheshire City News, Liverpool Courier, Pioneer Mail, Builder, Irish Times, Derby Express, Architect, North Wales Chronicle, City Press, Hackney Mercury, Morning Leader, Scotsman, Yorkshire Post, Bristol Mercury, Citizen, Courrier de la Presse, Leeds Mercury, Sanitary Record, Optician, Liverpool Daily Post, Detroit Tribune, Reading Mercury, West Middlesex Standard, Weekly Free Press and Aberdeen Herald, Hertfordshire Mercury, Local Government Chronicle, Dairyman, Surrey Advertiser, Toronto Signal, Evening Bulletin, Philadelphia Mining Journal, Cape Times, Local Government Journal, Watford Chronicle, Kelso Mail, Peterhead Sentinel, Worcester Daily Times, Australian Medical Journal, Australasian Medical Gazette, General Advertiser (Dublin), Walton News, Western Mail, Banffshire Journal, Southport Visiter, Portsmouth Mail, &c., &c.*

Valedictory Address,

Delivered at the termination of the Seventieth Session of the Army Medical School, Netley,

BY SURGEON-GENERAL SIR JOSEPH FAYRER, K.C.S.I., M.D., F.R.S., Q.H.P.,

HONORARY PHYSICIAN TO THE PRINCE OF WALES; LATE PRESIDENT OF THE MEDICAL BOARD, INDIA OFFICE.

IT is rather more than twenty years since my official relations with the Army Medical School at Netley began, and this is not the first time I have had the honour of addressing the surgeons on probation on an occasion similar to that for which we are now assembled, for I find that on April 1st, 1875, I addressed them at the opening of the school, and on Feb. 3rd, 1879, I had the privilege of presiding at the distribution of prizes. During the intervening period of twenty years I have had the opportunity of watching the progress of the school, have done so with great interest, and have noted with much satisfaction the gradually increasing good influence it has exerted on the medical department and through them the medical services generally. It is a subject for congratulation that the school continues to prosper, despite the vicissitudes and changes it has undergone; its very existence even has been menaced, but happily it has survived these dangers and has so well maintained its prestige and asserted its utility that we may hope that (the need for its existence being so well established) any future changes will be only such as tend to the expansion of the teaching of those subjects especially relating to the duties of the military medical officer which were originally contemplated when it was founded, and which can nowhere be so well taught as they are here. Deeply interested in the service in which my life has been passed, and knowing by experience how valuable is the character of the education and training imparted here, I have always wished to see the teaching of this school extended over a longer period of time and its sphere of utility enlarged, and have hoped that in process of time its benefits might be made available for other medical men destined for a public career in the sanitary and civil medical services of the country, including the colonial, as well as for the officers of the Army and Indian Medical Department. I am much impressed with the belief that such a modification in the present system would be of great benefit alike to the Service and the individual medical officers, for, however perfect may be the scheme of education in the great civil medical schools and universities, however highly specialised may be the teaching of certain subjects in any one of them, that combination of special subjects peculiarly needed in the public medical services, especially in the Army and India together with instruction in military and administrative questions—to say nothing of the advantages of *esprit de corps* acquired by association in a great school before entering the actual service—can never be imparted or acquired as thoroughly elsewhere as it can here. In my humble opinion, the time now allotted for residence at Netley, considering the varied and special nature of the curriculum, is hardly sufficient, and I do not hesitate, therefore, to say that I trust the period of study for probationers may ultimately be extended. Officers having this longer training and special education would be even better qualified than they are at present to meet all emergencies and to carry out the scientific investigations so imperatively demanded in these days, when great problems of etiology as well as of preventive medicine are exciting so much interest and are straining to the utmost the resources of practical scientific research for their elucidation. In this respect this great school is peculiarly well endowed and admirably equipped for the means of such teaching, and the teachers are alike forthcoming; more time only is required to do full justice to both. And here I would, through you, urge on your successors the supreme importance of diligent use of the period of probation here. The time is so short, the subjects are so important, that without close and unremitting work and attention the necessary standard may not be attained and disastrous failure result. This in my experience of Netley is rare, but it *does* occasionally happen, and I would urge you to impress on your friends and successors the importance of bearing it in mind.

When I last addressed the young officers (1879) who had just gained their commissions, I expressed my hope and belief that better prospects were foreshadowed and might be anticipated for the Medical Services. Times had been, and indeed still were, unfavourable, a feeling of disquietude and unrest prevailed, and there was a sense of general dissatisfaction with the existing condition of things. That there was reason for this I think cannot be doubted, nor can I say it is altogether extinct now; but I ventured then to suggest that possibly the difficulties did not all arise from outside, and that to a certain extent, perhaps, the obstacles might be found within the Service itself, and that, if it were so, it behoved the medical officers to see to it that such internal causes should be removed. I reminded the young officers that the social and educational influences of a great institution like Netley are calculated to foster and develop (amongst other things) that *esprit de corps* which so greatly conduces to real stability in any department of the public services. I pointed out also that the position of the military and Indian medical officer offers such advantages as ought to command a supply of the *élite* of our Universities and medical schools. All this I repeat to-day; and I am glad to think that as time advances there has been, on the whole, a favourable change. Many men of high culture are competing for the appointments, but indications are even now not wanting of a doubting confidence, for I am told that the competition is less keen than it has been; still, the general tone and feeling in regard to the Services have improved. Unfavourable conditions have been mitigated if not removed; the importance of the medical officer's work is more appreciated and his true place in the great military organisation better understood, and, as a consequence, more authority is attached to his opinion and more weight to the importance of his duties, which are concerned with not merely sickness and wounds, but the well-being and sanitary condition of those under his care. Until a few years ago the military status of the medical officer was insufficiently defined. It is true he held what was called "relative" or "comparative" rank, but this, however, served but imperfectly to endue him with that authority which is essential to his position as an important and indispensable officer of the Army. It had long been felt that his status required more exact definition, but there were always certain obstacles to this which stood in the way. It was argued, I believe, that however necessary the medical officer might be—and that he is so was not disputed or denied, at all events by reasonable persons—yet that substantive military rank could not appropriately be conferred upon him. This view, it would seem, could only have arisen from a misconception of the true nature of a commission. The idea that the title of Lieutenant, Captain, Major, or Colonel could only be held by that particular branch of the Service whose duty it is to direct the combative energies of the soldier was surely a mistaken one, for it is in the power of the Sovereign to confer such distinction on anyone, and it is conferred on officers of the military service who have no immediate connexion with mere combatant action, as is amply demonstrated by the fact that the officers who control the Commissariat, the Army Service Corps, nay, even the band master, now can and do, hold substantive commissions in one or other of those ranks. If it be considered necessary and possible that these officers should be so commissioned, it is difficult to understand why the same advantages should have been withheld from the medical officers, who, being so closely connected with all that concerns the health, discipline, the well-being and effective condition generally of the Army, need such warrant for their authority as much as do those of any other department. The concessions that have been made doubtless conduce to the interests of the Service by placing the medical officer in a more assured position and by defining more clearly the substantive rank and authority which he holds, though I must confess one has difficulty in appreciating the advantage of such a cumbrous title as that of "Brigade-Surgeon-Lieutenant-Colonel." Time, however, will probably modify such complex designations. Invidious distinctions implied in the terms "combatant" and "non-combatant" can have but little real significance in these days, when the records of almost every action fought or position defended show how equally risks are shared by the medical and the other officers, whilst the number of Victoria Crosses worn by them is a curious comment on the use of the term "non-combatant" (with its present meaning) as applied to the medical officer. But let me repeat what I said on a former occasion, which is that your military rank gives you no title, nor does it call upon you in ordinary cases to assume

Digitized by Google

the place or duties of the combatant officer, and I hope I need not even hint at the impropriety and bad taste of assuming any position to which your own, as members of a learned profession, should make you indifferent, for, whatever your military rank may be, you are first of all medical men. Still, withal, you are soldiers, and it may happen, as it often has done, that you have in an emergency to take the place of your combatant brethren. Should it fall to your lot to do so you will be prepared to show that you are as ready for this as for any other duty. Two brilliant examples are even now before you in the cases of Surgeon-Major Robertson, who as a political officer contributed to the defence of Chitral, and of Surgeon-Captain Whitchurch, who risked his own life and fought his way through the enemy, carrying and protecting his mortally wounded comrade. Both these officers have recently received recognition of their services. If you confine yourselves, therefore, to your own distinct sphere of duty, which is ample and sufficient, the benefit of your influence will be appreciated; if you overstep it you will be in a false position; your efforts for good will be minimised and your counsels neglected if not ignored. Remember also that though your status in the Service is now—as it should be—assured by your military rank, so much of your influence for good depends upon personal character that you should endeavour to maintain that at the highest standard.

Gentlemen, let me now congratulate you upon the successful termination of your career at Netley, and upon having achieved the great object of your ambition—your commissions in the Service; and especially I would congratulate those of you who have obtained prizes bearing the names of Sidney Herbert, Edmund Parkes, Ronald Martin, and De Chaumont—names that will be honoured and respected wherever they are mentioned and medical science is appreciated. They have conferred lustre on the Service generally and upon this school in particular. They deserve well of their country, and they may rightly be held up to you and other young men as models for imitation. Let these prizes be an inducement to you to endeavour to follow in the steps—long and laborious they may have been—which led to their great distinction, and which will lead you too, perhaps, if you follow in them, to a similar pre-eminence. These prizes should also be an incentive to you to endeavour to maintain and increase the prestige which they now reflect upon you, whilst at the same time they should serve to remind you of the efforts by which that success was obtained and the obligation imposed upon you of continuing to merit it. To those of you—and it is of necessity the majority—who have not been equally successful I would say that you have won one great prize in securing your commission; there are still others to be won in the career before you, and many advantages to be gained, if you will only work perseveringly and seize the opportunities when they present themselves. Both India and the army offer many paths to eminence—India especially does so—and to one or other of these goals you will surely attain, if having determined to do so at the outset you earnestly persevere. It has been said that the public services offer little inducement to exertion; that they present, after all, but a somewhat dull level of monotonous equality; and that talent, energy, zeal, and special devotion to one or other of the branches of science are but of litttle avail and lead to nothing. This is not the case—least of all is it so in India, where many and varied appointments are attainable and await the earnest worker. They are, at least, filled at the present moment by medical officers, and though in this respect, perhaps, India is not so fertile as it may have been in past times, it still offers opportunities of professional and scientific advancement which are excelled by those of no Service in the world. I am afraid I may not hold out to you such prospects of honours and distinctions as fall to the lot of some other departments of the public service, but even in this respect there are signs of improvement, and it is possible that in the future such recognitions as are accorded to military, political, and civil officers of long and distinguished service may fall to your lot likewise. But, after all, when you adopted the profession of medicine as a career you did not contemplate such rewards as the chief object of your ambition. It was rather, I take it, the exercise of a noble profession, the advance of knowledge, the welfare of your fellow-creatures, and the satisfaction of feeling that you aim at the almost god-like power of relieving suffering, saving life, and promoting the sanitary, moral, and material welfare of your fellow subjects that influenced you, and to this you may in a measure certainly attain. Great wealth you will perhaps not acquire, but a competency you may certainly rely on—sufficient, at any rate to relieve you from those carking cares and pecuniary anxieties which so often retard the pursuit of knowledge and the progress of the individual. In most cases you may rightly look forward to being able to provide for your families and, under favourable circumstances, even to acquire a certain amount of wealth. You will, at all events, be able to lead useful and honoured lives, whilst you will acquire "troops of friends," and it may well be that from among you shall arise another Parkes, Falconer, Waring, Hooker, Longmore, Maclean, Aitkin, De Chaumont, or David Smith, or perhaps even a worthy successor to the great biologist and philosopher who has so recently gone to his rest—for Huxley and the men I have mentioned, to whom might be added many others, at least began their lives and laid the foundations of future eminence in one or other of the medical services.

On the last occasion upon which I had the privilege of presiding at a meeting of this kind I had but recently become officially connected with this school as a member of the Senate. The duties were most congenial to me, for I had always taken much interest in the education and training of medical officers. The anticipations that I then formed in reference to the objects and results of this great school have been fully justified; and I now, having ceased to occupy that official position, look back with great pleasure upon the years that have passed in connexion with it, and the regret that I feel on the closing of my official connexion with the school is tempered by the knowledge that my successor, Surgeon-Colonel Hooper, will strive to guard and promote your interests with all the zeal, earnestness, and ability which characterised him in India, and have led him to the position he now occupies. I have watched with keen interest the career of your predecessors on these benches, and have been gratified to learn how thoroughly many of them have done credit to the teaching they have received here; whilst I deeply regret that this almost general rule has not been without exception. The severance of my official relation with the school in no way diminishes the interest I take in it; and I look forward with pleasure to the privilege of being present on such occasions as these, and of still watching its progress and the influence that it will, I hope, continue to exert in elevating the Medical Department and maintaining it in the position it should take amongst the other great public services of this country.

It only remains for me now to impress briefly upon you the importance of the duties that you will be called upon to perform. To those of you who are destined for the military service of this country will be entrusted the care of the health of our soldiers at home and abroad. Upon you it will devolve to advise the authorities upon all sanitary questions and whatever concerns the physical well-being of the army under your care. In the event of war—and who can say how long we may remain at peace?—the treatment of the sick and wounded will be your special care. To you, also, it will fall to investigate the laws that govern the origin and diffusion of epidemic and other forms of disease, and all that concerns the soldier's health. Already, through the influence of your predecessors, the death-rate of our soldiers in India has been reduced within the last fifty years from something like sixty to thirteen per mille, and no doubt this mortality is susceptible of further diminution, whilst side by side with the reduced death-rate will continue an amelioration of the conditions of life generally. Nor will your duties be limited to those of a purely military medical character, for there are some special spheres of action and appointments open to those who may aspire to them. To those of you who are destined for the Indian Medical Service similar but even wider prospects are open, for there your duties will be of a still more varied character. Problems concerning disease, the laws regulating the rise and spread of cholera, fever, and other epidemics—their pathology, etiology, and therapeutics—still need and claim further investigation and research. Or, apart from medicine and hygiene, the whole range of natural science, involving zoology, botany, meteorology, and ethnology, afford matter for investigation and fields for research which are yet comparatively unexplored. Your education and scientific training fit you to take up and deal with these subjects, and I would suggest to you the advantage of doing so—i.e., of having some other occupation than that which is concerned with medicine alone. You have thus before you, to whatever Service you belong, the prospect of an interesting, useful, and profitable career. The measure of your success will be that of your own exertions. If you exercise the ordinary precautions

Digitized by Google

for preserving health you may have every reason to hope that you will pass through it successfully—and, I trust, satisfactorily—and may return to this country in health and vigour and with large experience with the prospect of doing useful work at home—it may be in this great school. I will not detain you longer than to say that in bidding you farewell I wish you every prosperity and success, and trust that your highest aspirations may be realised.

Address in Physiology

ON

INTERNAL SECRETIONS.

Delivered at the Annual Meeting of the British Medical Association at London, Aug. 2nd, 1895,[1]

By EDWARD A. SCHÄFER, F.R.S.,

JODRELL PROFESSOR OF PHYSIOLOGY IN UNIVERSITY COLLEGE, LONDON.

MR. PRESIDENT AND GENTLEMEN,—My definite subject—the subject of internal secretions is one of far-reaching interest, although its full importance has only lately come to be recognised. A secreting organ is one which separates certain materials from the blood and pours them out again, sometimes after effecting change of some sort in them, usually upon external surfaces, or at least upon surfaces which are connected with the exterior. These are the secretions which are most commonly known under that name. On the other hand, some secreted materials are not poured out upon an external surface at all, but are returned to the blood. These may be termed internal secretions, and they may be and are of no less importance than the better known and more fully studied ordinary or external secretions. The name of gland is one which is usually applied to a secreting organ; and to those which have been believed to furnish only internal secretions the name "ductless glands" has been applied. It is not, however, the ductless glands alone which possess the property of furnishing internal secretions, for it is clear, according to our definition, that this will apply to any organ of the body. Every part of the body does, in fact, take up materials from the blood, and does transform these into other materials. Having thus transformed them they are ultimately returned into the circulating fluid, and in that sense every tissue and organ of the body furnishes an internal secretion. Moreover, certain important glands which are provided with ducts possess not only the faculty of yielding an external secretion, but have equally important, if not even more important, functions in connexion with internal secretion. Thus both the liver and the pancreas are as essential to life, by virtue of the internal secretions which they furnish to the blood, as they are by their better known external secretions. The evidence of this is complete. The entire removal of either of these organs causes death, and this is due to the removal of the influence which they exert on the metabolism of the body by the loss of their internal secretions, not necessarily to the loss of their external secretions; for in the case of the liver it is well known that the bile may be diverted by a fistulous opening without any serious interference with the vital functions, and the same is the case for pancreatic juice. The kidney is another instance. It might, indeed, at first appear that a similar statement will not apply so well here; but it has been shown by the researches of Dr. Rose Bradford that the kidney is not a real exception to the rule laid down, for enough of the kidney substance may be left to carry on the excretory products of the body, and yet the removal of the remainder of the organ may cause such disorganisation of the nitrogenous metabolism of the body as to lead speedily to wasting and death.

The same result is not obtained with all glands. The salivary glands may be entirely removed without any marked symptom supervening. And this is also well known to be the case with the mammary glands. On the other hand, removal of the generative glands leads to marked alterations in the development of other parts of the body. In the last-mentioned case the changes are without doubt produced through the nervous system, and are not connected with the internal secretion of the glands; and with respect to the salivary and mammary glands we may assume that, although they yield an internal secretion of some sort to the blood, it is of the same nature as that yielded by other organs, and that such other organs may act vicariously for those removed. This is, however, inapplicable to the liver, the kidney, or the pancreas; removal of which or restriction of their internal secretions is inevitably followed by a fatal result.

I do not propose to dwell further upon the internal secretions of the liver and kidney, and for contrary reasons—namely, that in the one case the subject has become too large for the limits of a short address; and in the other because the subject is one with regard to which we have at present too little information. But before leaving the liver I would point out that it affords an excellent illustration of the fact that internal secretions may, like ordinary or external secretions, either serve some useful purposes in the body, or may be formed only to be got rid of (excretions). The formation of glycogen and sugar is an example of a useful internal secretion—that of urea—of what would be termed in the ordinary sense an excretion, although it is not actually got rid of by the liver, but is produced by that organ only to be got rid of by the kidney. The internal secretion of the pancreas may detain us somewhat longer. Among the racemose secreting glands the pancreas offers a peculiarity of structure which in the first instance it may be well to note. For we meet here, besides the secreting alveoli and ducts, a peculiar epithelium-like tissue which occurs in isolated patches throughout the organ and which is characterised by its extreme vascularity. These islands of epitheloid tissue are quite characteristic of pancreas. We know of no other externally secreting gland which contains them.

Now it was formerly believed that the sole function of the pancreas was to yield pancreatic juice, and this, it must be confessed, is in itself a sufficiently important function, seeing that this fluid contains ferments which act on all the principal organic constituents of the food. Before 1889 it had indeed been remarked that cases of glycosuria occurring in the human subject were frequently associated with disease of some kind of the pancreas. Frerichs found that 20 per cent. of the total number of cases of diabetes which came under his notice were accompanied by obvious changes in the pancreas. This observation led to experimental inquiry. Claude Bernard had long previously attempted to entirely remove the pancreas, but all his attempts were unsuccessful, in so far that the animals speedily succumbed. In 1889, however, the operation was successfully performed by Von Mering and Minkowski. They found that all cases in which the entire pancreas was removed the operation was followed within the space of a very few hours by the appearance of sugar in the urine, and this to a great extent—as much as 5 to 10 per cent. being found even in fasting animals. Accompanying the condition of glycosuria there is also produced polyuria; and these conditions occur even under a purely flesh diet, and are accompanied, as might be supposed, by a rapid wasting, and followed within the space of fifteen days or less by death. This result is not due to the loss of the pancreatic secretion, for, as we have already seen, the pancreatic juice may be diverted by a fistula, and the animal may remain in perfect health. Nor is it due to the loss of the secreting structure; for it has been found possible to destroy the secreting structure of the organ without the supervention of diabetes. This was done successfully by Schiff in 1872. Schiff's method, which was a repetition of experiments by Bernhard, was the injection of paraffin into the duct of Wirsung. In Bernhard's original experiments all the dogs operated on speedily died; but this was probably due to accidental causes, and not to the actual destruction of the pancreatic tissue; for in Schiff's experiments the dogs survived and remained in perfect health. The fact that removal of the pancreas is followed by glycosuria was not at that time known, and the appearance of sugar in the urine was not therefore looked for by Schiff. But there can be no doubt of the absence of any severe form of diabetes, because the animals underwent no wasting.

Quite recently the experiment has been repeated by Thiroloix, who found that, although the gland was reduced by the process of atrophy supervening on the injection to a mere rudiment, symptoms of diabetes do not occur as when the whole gland is removed. It is now well known that if a

[1] Professor Schäfer intended to illustrate his address by lantern slides, but the hall being unsuitable for this he gave his audience a good idea of his meaning by tracing the curves with his finger.

Digitized by Google

portion of the pancreas be left, about a quarter or rather more, no glycosuria appears. In the great majority of cases the animals remain healthy; so that it is clear that a portion only of the gland can prevent the diabetic symptoms. Nor need the portion of gland which is left remain in its ordinary situation. It or a portion of the gland from another animal may, in fact, be grafted either elsewhere into the peritoneal cavity or under the skin. Provided the grafting be successful, and the portion of the gland employed of sufficient size, removal of the pancreas is now no longer followed by the usual symptoms. The animal may remain, in fact, in perfect health. But, if at any subsequent time the grafted portion of pancreas is removed, diabetes supervenes, and the animal dies within a short time, as after a primary removal. Now it has been shown by Thiroloix that the grafting of a portion of pancreas, the secreting part of which had been destroyed by injection of paraffin along the ducts, is also efficacious in preventing the advent of diabetes after removal of the pancreas. We must therefore assume that the material, whatever it may be, which is furnished by the pancreas to the blood, and which prevents excessive formation of sugar in the blood and in the urine, must be formed by some other constituents of the gland than the secreting cells; for there is every reason to believe that these cells are eventually completely destroyed after the ducts have been blocked in the manner described.

[Professor Schäfer here considered the various theories which have been put forward as to the functions of the pancreas as an internally secreting organ, and went on to say:]

The only fact that appears certain in connexion with the manner in which the pancreas prevents excessive production of sugar within the body is that this effect must be produced by the formation of some material, secreted internally by the gland and probably by the interstitial vascular islets, and that this internally secreted material profoundly modifies the carbohydrate metabolism of the tissues.

The next internal secretion which I propose to consider is that of the thyroid gland. The process of study is in one sense simpler in this case, since there is no external secretion. That the thyroid gland is a secreting gland no one who studies its structure and its mode of development can well doubt; except that it is unprovided in the adult state with a duct it has all the features of structure of secreting glands. It is formed of alveoli which are lined by epithelial cells, and these cells have been observed to exhibit changes after treatment with pilocarpin in no way dissimilar to those changes which have been noticed under like circumstances in the cells of true secreting glands. Further, we can observe the secreted material within the vesicles of the thyroid in the form of the substance known as "colloid."

[Professor Schäfer then gave a *résumé* of the physiological investigations on the thyroid gland and an account of the symptoms which follow thyroidectomy. He continued:]

Various theories have been advanced to account for the effects of removal of the gland. H. Munk holds, or until lately held, that the effects of removal are entirely due to interference with adjoining nervous structures in the neck. But this, as in the similar theory propounded to account for the effects of extirpation of the pancreas, is absolutely negatived by the results of thyroid grafting. Besides this theory, which must, it seems to me, at once be dismissed, there are two others which may be regarded as disputing the ground between them. Of these the one may be called the theory of "autotoxication" and the other that of "internal secretion." The autotoxication theory assumes that there is a certain toxic substance which is constantly tending to accumulate in the blood, and which it is the duty of the thyroid gland to render innocuous and to remove. According to this, the function of the thyroid would be primarily excretory. This view is supposed to be supported by the statement that in animals which are dying after removal of the thyroid the blood is toxic for other animals, and especially for those which have already had the thyroid removed, although only a short time previously, and before the symptoms of thyroidectomy have had time to develop. It is not stated what the probable nature of this substance is, or by what tissues it may be formed. The "internal secretion" theory would explain the phenomena of extirpation as due to the absence of a secretion which is formed within the thyroid, and which is passed into the blood, possibly through the medium of the lymphatics: a secretion which is necessary for certain of the metabolic processes within the body, and especially for those connected with the nutrition of the central nervous system and of the connective tissues. For, in the first place, beneficial and not toxic effects follow the exhibition of thyroid juice both in cases of thyroidectomy in animals and in myxœdema and other affections in man; and, secondly, if we investigate the physiological effects of extract of thyroid gland, whether prepared with water or glycerine, and whether previously boiled or not, we find that it produces a distinct action upon the bloodvessels, so that the blood pressure markedly falls although the beats of the heart remain at about the same rate and of the same strength. This lowering of the blood pressure without influencing the action of the heart can only be produced in one way—namely, by increasing the calibre of the arteries. Before this effect upon the blood pressure was discovered it had been shown by Dr. George Oliver that the exhibition of thyroid juice or other preparations of thyroid in the human subject has a tendency to increase the calibre of the radial artery. It would seem, therefore, that the juice of the thyroid and extracts which are obtained from the gland have a distinct physiological effect upon the vascular system. In connexion with this it is of interest to recall the observations of Lorrain Smith upon the effects of thyroidectomy in altering the gaseous exchanges—that is to say, the oxidations within the bodies of animals. Lorrain Smith found that in animals which have been deprived of the thyroid body the reaction to changes of temperature was abnormally rapid. When normal animals are exposed to a cold atmosphere the production of carbonic acid becomes increased consistently with the increased oxidation which we know to occur, but this increase of production of carbonic acid does not take place immediately, but only comes on after a certain period of time, the temperature of the body being in the meantime maintained normal by those physical changes which occur in the circulation, and which allow the quantity of blood brought to the skin, and the amount of heat thereby lost from the general surface of the body, to be varied. Now it is precisely these vaso-motor changes which appear to be lacking after removal of the thyroid; for the production of carbonic acid becomes almost immediately increased by exposing the thyroidectomied animals to a low temperature. That the thyroid gland yields an internal secretion which effects a useful purpose within the body appears to result conclusively from these facts, and the effects which follow thyroidectomy are probably due to the loss of that secretion. Whether the gland also possesses the function of destroying toxic products of metabolism which would otherwise tend to accumulate in the blood is a point which requires the production of more conclusive evidence before it can be regarded as established.

[Professor Schäfer next considered the pituitary body, quoting experiments which went to show that this gland supplied an internal secretion which caused contraction of the heart's arteries. He proceeded:]

Lastly, I propose to ask you to consider the internal secretion of the supra-renal bodies. The immense importance of these glands in nutrition was indicated by Addison, who, in 1855, pointed out that the symptoms of the disease now known by his name are associated with pathological alterations of the supra-renal capsules.

[Here Professor Schäfer referred to the symptoms of Addison's disease, as well as to the experiments of Brown-Séquard and other observers. He then continued:]

Experiments upon normal animals with extracts of supra-renal have been performed by a number of observers, but by all in a very incomplete manner. For the most part they have been satisfied to subcutaneously inject extracts made with water and other menstrua, and to observe the symptoms, if any, which result. As a matter of fact, in some animals which are so treated there are no obvious symptoms. The guinea-pig will stand a large subcutaneous dose of supra-renal extract without showing any symptoms at all, or with, perhaps, only a slight acceleration and increase of the force of the pulse. The same appears to be the case with the cat and with the dog, unless a very large dose be injected. Rabbits, on the other hand, are extremely susceptible to the influence of supra-renal extracts. If a large dose be given the animal may succumb within half an hour. If, on the other hand, the dose be only moderate in quantity, it may not show any symptoms at all for some hours, and then it may suddenly succumb. This primary absence of symptoms has been especially noted by Foà and Pellacani, who state that in many of the dogs which they experimented upon in this way there were no symptoms at all apparent on the day on which the injection was given, but that the next

Digitized by Google

morning the animal was usually found dead. The cause of death, it may be added, in this case is not by any means clear. Foà and Pellacani have supposed that it may be due to paralysis of the respiratory centre, but the slight effect which intravenous injection of supra-renal extract produces upon this centre does not lend support to this conjecture.

We may next proceed to consider the physiological effects of intravenous injection of supra-renal extract. The facts which I am about to put before you are new; they are the result of experiments by Oliver and myself, which have been carried on in my laboratory during the last two years.[2] They show conclusively that the medulla of the supra-renal capsule contains a dialysable organic principle, soluble in water, and not destroyed by boiling for a short time, which produces a powerful physiological action upon the muscular system in general, but especially upon the skeletal muscles, the muscular walls of the bloodvessels, and the muscular wall of the heart. A certain amount of action is also manifested upon some of the nerve centres in the bulb, especially the cardio-inhibitory centre, and to a small extent upon the respiratory centre.

The effect upon the skeletal muscles is well shown in the frog, but can also be seen in mammals. The contraction of a muscle in response to a single excitation of its nerve is as ready as in the normal animal; but it is greatly prolonged, so that the result is comparable to that produced by a small dose of veratria, which, as is well known, has the effect of enormously increasing the contraction resulting from a single stimulation of the muscle or its nerve. It is in no way comparable to a curare effect, for the muscles remain as excitable through their nerves as before. It is therefore an effect entirely different from the so-called autotoxication paralysis which is stated to result after removal of the supra-renal capsules in animals, and the material which is extracted by water, therefore, from the supra-renal capsules is certainly not the same material that is said to accumulate in the blood after the removal of those organs. The action upon the circulatory system may be divided into the action upon the heart and the action upon the arterial system. Upon the heart the effect differs according as the vagi are cut or uncut. When the vagi are uncut, and the heart is therefore still in connexion with the cardio-inhibitory centre in the medulla oblongata, the action of supra-renal extract is to slow, and even to entirely stop, the contraction of the auricle. Under the circumstances the ventricle continues beating with an independent slow rhythm. The result is to cause the pulse to be very slow. On the other hand, when the vagi are cut or their cardiac ends paralysed by atropine the effect upon the heart is precisely the reverse. The strength and frequency of the auricular contractions are markedly increased, and those of the ventricle are correspondingly augmented. This naturally has the effect of sending a vastly greater amount of blood into the arteries, which by itself would alone produce a great rise in the arterial pressure. The direct action upon the arteries is, however, quite as marked as that upon the heart. If the blood pressure be taken in a dog in the usual way by connecting a mercurial manometer with the femoral artery, and if a minute dose of supra-renal extract be now injected into a vein, it is found that even with the vagi uncut and the heart therefore slowed by the action of the extract the blood pressure rises considerably. But with the vagi cut or paralysed by atropine the rise can only be characterised as enormous. The contraction of the arteries is further exemplified by the fact that if an organ, such as a limb, or the kidney, or the spleen, be enclosed within a plethysmograph the instrument indicates an enormous diminution in volume of the organ, which can only be accounted for by a contraction of its arterioles.[3] This contraction is produced by the direct action of the drug upon the muscular tissue of the smaller arteries and not indirectly through the vaso-motor centre, for it obtains in the mammal equally well with the spinal cord cut or the bulb destroyed, or even in the case of the arm after the brachial plexus has been severed. In the frog it is produced also with the brain and spinal cord completely destroyed and salt solution containing supra-renal extract allowed to flow through the arteries.

Under these circumstances the flow of fluid, which without the supra-renal extract may have been comparatively rapid, becomes almost completely stopped, and this can only be due to the direct action of the extractive substance upon the muscular tissue of the smaller arteries. The enormous rise of blood pressure which is got after the vagi have been cut is shown in the tracings. The pressure may rise to four or five times its original height; I know, in fact, of no other agent which will produce such an enormous increase of pressure except direct stimulation of the vaso-motor centre. It is not the case, however, that this centre is stimulated by the drug, as has been erroneously supposed by Cybulsky, for, as we have seen, the action is essentially a peripheral one. The effect passes off in the course of a few minutes. After a dose, no matter whether small or large, has been injected into a vein and has produced the results which we have seen the bloodvessels slowly resume their ordinary calibre, the augmentation and increased frequency of the heart's beats become gradually lessened and the blood pressure recovers its normal condition. Whilst the pressure is raised under the action of the supra-renal, there is apparently no possibility of inhibiting the arterial contraction; even the strongest stimulation of the depressor nerve, which under ordinary circumstances produces through the vaso-motor centre a marked dilatation of the arterioles, is without result during the activity of this extract. The question naturally arises, How is it that the effect so soon disappears? In what manner is the active principle eliminated? It is not eliminated by the kidneys, for the effect passes off just as quickly, even although the renal arteries are clamped. It is not eliminated by the supra-renals themselves, for the same fact holds good for the supra-renals. It passes off almost equally quickly if the aorta and vena cava are tied in the upper part of the abdomen, so that there is no circulation of blood whatever in the abdominal organs. It is not oxidised or otherwise destroyed by the blood, for it retains its full potency even after it has been twenty-four hours in contact with that fluid. The most probable explanation of the disappearance of the effect seems to be that the active principle becomes packed away and eventually rendered innocuous in certain organs. That the muscles take most part in this storage is probable from the fact that the physiological effects upon the skeletal muscles are manifested for a long time after the effects upon the heart and arteries have disappeared. One of the most interesting and important facts regarding the material which is yielded by the supra-renals is the minuteness of the dose which is necessary to produce these results. As little as 0·0055 g. (5½ milligrammes) of dried supra-renal is sufficient to obtain a maximal effect upon the heart and arteries in a dog weighing 10 kilogrammes. For each kilogramme of a body weight, therefore, all that is necessary to produce a maximal effect is 0·00055 g. (little more than half a milligramme).

Now we have shown that the active principle is contained only in the medulla of the gland, not in the cortex, and the medulla in all probability does not form more than one-fourth of the capsule by weight. Of the dried medulla certainly not than nine-tenths is composed of proteid and other material which is not dialysable, and which otherwise does not conform to the chemical properties which have been ascertained to belong to the active substance; so that, if we take all these facts into consideration, we find that, in order to produce the maximal effect, a dose of not more than fourteenth-millionths of a gramme per kilogramme of body weight is all that is necessary. Now it is certainly true to say that one-fourteenth of this dose will produce some effect, although not perhaps a very large one. We thus arrive at the fact that this material given in the proportion of not more than one-millionth part of a gramme per kilogramme of body weight, which would be equivalent to $\frac{1}{15000}$ gr. (less than $\frac{1}{100}$ gr.) for adult man, is still sufficient to produce very distinct physiological results.

It may well be that the supra-renal capsule is continually passing into the blood this active material, which, although present in minute quantities, may be supposed to produce an effect which is beneficial for the performance of the functions of muscular tissue, and especially the muscular tissue of the vascular system. It has, in fact, been stated by Cybulsky that the blood of the supra-renal vein contains a sufficient amount of the active principle of supra-renal extract to produce marked physiological effects. I have made three very careful experiments in an endeavour to confirm this statement, but I have not been able to find that the blood of the supra-renal vein does actually contain a sufficient amount of this material to produce, even in doses of as much as 10 c.cm., any more result than venous blood generally. But, whether

[2] The chemical work in connexion with these experiments has been carried out by Mr. B. Moore.

[3] In man the effect of taking supra-renal extract by the mouth is to produce a general diminution in calibre of the arteries as measured by the arteriometer.—Oliver.

Digitized by Google

we are able to show it experimentally or not, there is, I suppose, very little doubt of the fact that the materials formed pass somehow or other into blood; and, when we compare these results of supra-renal injection with the converse effects obtained from the removal of supra-renals and from disease of supra-renals, we can come to no other conclusion than that we have before us a well-marked instance of an internal secretion. The general results to which we are led from a consideration of these facts, and others to which I have had no time so much as to allude, point strongly in favour of a theory of internal secretions, and it is obvious that such internal secretions may be of no less importance than the better recognised functions of the external secreting glands. These internal secretions have to be definitely reckoned with by the physician, while at the same time the therapeutist will be able to avail himself of the active principles which they contain, and in certain cases to use extracts of internally secreting glands in place of the hitherto more commonly employed vegetable medicaments. That the subject has a vast future there can be no doubt, for, in spite of the advances which have been made in elucidating it during the last few years, a great number of points still remain obscure. Nevertheless, the way which the physiologist has attempted to show may be followed by the practitioner, and the result of these physiological experiments may now be utilised for the diagnosis and treatment of disease.

ON THE PREVENTION OF PHTHISIS.

BY JAMES NIVEN, M.B. CANTAB.,
MEDICAL OFFICER OF HEALTH TO THE CITY OF MANCHESTER.

IN the issue of *Public Health* for December, 1894, is a paper read by Dr. Henry Armstrong before the North-Western Branch of Medical Officers of Health on the above subject, in which he does me the honour to quote my name in connexion with preventive measures. He does not, however, agree with the summary of measures which he ascribes to me as being those on which I should rely. This summary reads thus: (1) notification (compulsory) as in fevers; (2) isolation (with legal procedure for breach of law, as in fevers) &c.; (3) disinfection; and (4) diseased meat (destruction of). Now in the issue for April, 1893, of the same publication I have clearly set out the lines of preventive action on which I should go, and these I will repeat as a basis of comment; but before doing so I should like to say that, no doubt unconsciously, Dr. Armstrong has quite misunderstood my position. I have never proposed isolation with legal procedure for breach of law as in fevers, nor have I thought of such a proceeding. On the contrary, I am under the impression that an isolation hospital would be regarded as a boon by many families one of whose inmates was phthisical, and that there would be no need of compulsion, which I quite agree with Dr. Armstrong in regarding as impracticable. Then, again, I consider the destruction of tuberculous meat as by no means so important as many other precautions, although, of course, not a thing to be neglected. In the paper in question I do not think that I have even mentioned diseased meat. That subject was raised by Dr. Armstrong himself at the same meeting of the Society of Medical Officers of Health at which I gave the paper alluded to, and I there mentioned that the North-Western Branch of the Society had passed a resolution that the carcase of an animal should be condemned if any tuberculosis was found in it; but of the proposals which I put forward it formed no part. Then, again, disinfection of rooms should be carried out, if possible; but this, again, is not part of the main front of my position. In fact, the proposals put forward to be condemned are, in part, not my proposals at all, and, where they are, they are not in their proper position of importance. Further, at the meeting in question I was present as a representative of the North-Western Branch to make proposals in regard to the infective element in tuberculosis. The various adjuvants in the establishment of infection, such as bad housing and bad personal habits, were necessarily, from want of time, put aside for the time being. In the causation of phthisis two factors are concerned—the conveyance of infection and those conditions of the system which favour the lodgment and growth of the tuberculous infection. The second factor plays a much more important *rôle* in the origin of phthisis than it does in many other diseases. It is, however, a *rôle* much more difficult to survey and discern than the more immediate part played by the transference of infective material, and it is also a *rôle* much more difficult to prevent. So far as it is preventable with special reference to tuberculosis, it would be prevented in the course of the measures adopted to intercept the conveyance of the tuberculous infection. For purposes of simplicity of treatment and clearness it is made incidental to the study of the direct transmission of tuberculous infection.

The main positions which it is necessary to bear in mind in planning out measures of prevention against the spread of tuberculosis are these:—1. Without the importation of the tubercle bacillus or its spores into the system tuberculosis cannot arise. 2. Phthisical people, especially in the later stages of the disease, discharge enormous quantities of tubercle bacilli and spores in their sputum. These are probably innocuous till dried. When dried and dispersed as dust this sputum is capable of lighting up tuberculosis. Schill and Fischer's investigations showed the prolonged vitality of tuberculous spores in sputum, and Cornet's researches established that the dust taken from a room in which a phthisical person was being treated was liable to convey the disease to guinea-pigs when taken from places which the sputum could not have directly reached. He found, also, that where the sputum had been carefully destroyed, such dust was not capable of reproducing the disease in guinea pigs. Moreover, the dust of streets, even where phthisical persons were known to spit, did not produce the disease in guinea-pigs. 3. Cornet's research on the mortality of Catholic nurses in Germany showed that intimate exposure to tubuculous dust of healthy individuals was followed by an enormous mortality, the period between exposure to this influence and death being between two and three years. Two years previously, in my report on the health of Oldham for 1891, I had given an account of a number of instances in which people who had died from phthisis had been intimately exposed to infection at a varying period before death, and arrived at the conclusion that the average latent period between exposure to infection and death was probably between two and three years. Again, in the report for 1890 I gave an account (which was reproduced in *The Practitioner*) of a series of 100 deaths from tuberculosis into which I had instituted an etiological inquiry. In more than half of these cases intimate exposure to infection was ascertained at a period which could be regarded as the starting point of the infection, and these comprised practically all the cases in which there was not some condition of health strongly predisposing to successful invasion by a comparatively small amount of infectious material. Dr. Heron, in his work on the Communicability of Consumption, gives a very interesting series of cases, collected by Professor Koch, of exposure to infection followed by tuberculosis. Perhaps the most striking of these clinical experiences are those in which exposure of a wound to tuberculous material has been followed by local tuberculosis, subsequently extending to the lungs. 4. Other tuberculous discharges besides sputum contain the infective matter, and are in like manner, though to a less degree, dangerous. 5. The infective matters from phthisical patients are capable of destruction by chemical agents and are easily destroyed by steam. In the shape of pure cultivations, and therefore as dust, they are readily destroyed by direct sunlight. This is a fact of cardinal importance. 6. Tuberculosis is widely distributed amongst the mammalia and is especially destructive to milch cows. In particular it has been shown experimentally that the milk of tuberculous cows is capable of lighting up the disease in guinea-pigs, especially if the udders are affected by the disease. There is, moreover, good reason on other grounds for believing that the milk from tuberculous cows is responsible for much of the tuberculous disease of children. So far as tuberculous meat is concerned, the grounds for believing it to be a source of abdominal tuberculosis are mainly experimental. 7. Phthisis is not rare amongst country people, and it is unfortunately only too common amongst milch cows. It was suggested to me by my friend Dr. Robertson of Oldham that the cycle was completed, so far as pulmonary phthisis is concerned, by the cows swallowing the tuberculous matter discharged from the lungs, which subsequently was voided by the cows undestroyed. Anyone acquainted with the condition of cowsheds in this country will at once perceive how very likely it is that phthisis is handed on in

Digitized by Google

this manner. The absence of light and ventilation, the frequent presence of tuberculous cows in the sheds, and the dusty condition of many of them, give to this suggestion a capital importance.

The proposals which I put before the society were based on these and kindred considerations. They were:

1. The memorandum of the North-Western Branch of the Society of Officers of Health or some equivalent form should be placed by sanitary authorities in the hands of all medical men, and as far as possible in the hands of all phthisical patients—"It would be well, also, to issue a brief handbill to every house, at all events in towns, giving simple directions as to the most important precautions. This was done in Oldham in 1887, 1888, and 1892." Last year a handbill, of which the following is a copy, was sent to every house in the city of Manchester:—

PRECAUTIONS AGAINST THE COMMUNICATION OF CONSUMPTION.

1. Consumption is an infectious disease likely to be communicated more particularly in damp, badly ventilated, and badly lighted houses and workshops.
2. It is usually communicated by the matters coughed up by consumptive people, which get dried and dispersed as dust, thus reaching the lungs of those susceptible to the disease.
3. Such matters should, therefore, never be allowed to get dry. For that reason they should not be spat on the floors of a house, but either into pieces of rag or paper, which should be at once burned, or into a hand-vessel containing water. This vessel should be emptied into the drains outside the house once a day, and then scalded and recharged with water.
4. Everyone affected with a chronic cough should take the same precautions as a consumptive person.
5. The same precautions should be observed in a workshop as at home.
6. Consumptive people should not spit into a pocket handkerchief, as both the handkerchief and their clothes are thus made infectious.
7. No one should spit on the ground inside any building or in a public conveyance.
8. The bowel discharges of consumptive people should be disinfected by being passed into a 15 per cent. solution of carbolic acid or simply into water, and the vessel, when emptied, should be at once scalded. Soiled clothing should be at once removed, disinfected, and afterwards boiled.
9. When it is settled that anyone is consumptive the house should be thoroughly disinfected, and the patient should be thenceforward confined to certain parts of the house. On a request made in writing to the Health Office disinfection will be carried out by the department free of charge.
10. The rooms occupied by a consumptive person should be kept well ventilated and well lighted. This will greatly aid in destroying the infection.
11. No one is more liable to inhale the dust from matters coughed up than the consumptive himself. The removal of infectious matter is, therefore, calculated to promote his recovery. Moreover, if these precautions are strictly carried out he need not be a source of danger to anyone.
12. It is the duty of the attendant to see that the above precautions in regard to the phlegm and discharges are observed, and also to see that every obstacle to sufficient lighting and ventilation is removed.
13. In case of death the house will be disinfected by the sanitary authority, if this is desired. A new tenant should not enter a house previously occupied by a consumptive person until such house has been thoroughly disinfected.
14. Amongst the agencies which act powerfully in causing consumption are damp dwellings and workshops, overcrowding, defective ventilation, occupations which involve the inhaling of irritating dust, and alcoholic excess. These should be avoided.
15. The milk from consumptive cows is very dangerous, especially to children. All milk should be boiled before use. As many animals suffer from consumption all meat should be thoroughly cooked.

JAMES NIVEN, Medical Officer of Health.
Public Health Office, Town-hall, Manchester, May 28th, 1894.

An admirable handbill has also been distributed by Mr. Vacher, medical officer of health to the county of Chester. The memorandum of the North-Western Branch was drafted by Mr. Paget, medical officer of health for Salford, in 1892, following on papers given by Dr. Ransome and myself to the branch in that year. It is admirably drawn and very well adapted for its object, which was rather to convey full information to phthisical families, and to serve as a basis for the medical attendant to give instructions upon, but is, I think, too detailed for a handbill to be generally distributed. To this general education of the public I attach the very utmost importance. If the public mind is not diligently and adequately prepared by the diffusion of information on the subject it is too much to expect that public bodies will be roused to take the necessary action, or that the general public will support them, or the officers whose duty it may be to carry out their instructions. Moreover, without any further proceeding whatever an immense impetus is thus given to the carrying out of precautionary measures. I have been assured that in Oldham it had become a very common practice to carry out preventive measures.

2. Tuberculosis should be made a notifiable disease—notifiable under the same Acts and under similar conditions to such diseases as scarlet fever. The inclusion of tuberculosis amongst notifiable diseases could be effected under Clause 7 of the Infectious Diseases Notification Act, 1889. What, then, are the reasons for proposing such a step? In the first place, whatever the concomitant conditions, tuberculosis is an infectious disease, the modes of propagation of which we know with great definiteness. It is especially in the later stages of the disease that the largest amounts of infectious material are being discharged from the system, and notification would, therefore, be valuable at any period of the disease. It is, moreover, especially in the later stages when phthisical patients require nursing and constant attention, and when through weakness their personal habits are liable to become most negligent that those in contact with them are exposed to the greatest amount of risk. I would propose at first to exclude from notification cases of closed glandular, bone, and joint affections, and only to deal with such cases as from the presence of discharges, whether from the lungs, mouth, skin, or bowels, are manifestly liable to convey the disease. I do not agree with Dr. Armstrong that the expense of such notification would be enormous, and I have given figures[1] to show that such would not be the case. If these data are regarded as unreliable, or if more satisfactory figures can be produced, it would be well to have them. One objection to notification it would be necessary to deal with—viz., the difficulty entailed by phthisical patients changing their medical attendant, as they frequently do. It is, in my opinion, indispensable, whether notification is to be—at first—compulsory or voluntary, that the usual fee of 2*s.* 6*d.* a case should be paid. To prevent, therefore, undue expense each patient reported would be furnished with a card bearing the date of notification of his case, which he would be required to produce on application for disinfectants, &c. Medical men would be requested to ascertain whether their patients had been previously notified, and not to notify a case a second time except on change of address. Even if such a precaution was not carried out I do not see that the expense would be such as to be a bar to notification. What are the objects to be gained by notification? In the first place the precautionary measures to be taken by the phthisical individual or his attendant would be prescribed and carried out. In the second place the conditions of the house favouring the spread of the disease would be ascertained and as far as possible removed. The conditions of work of other inmates of the household favouring the disease would be ascertained and as far as possible guarded against. Disinfection of the rooms occupied by the patient would be effected. The dangers of exposure of members of the family suffering from any condition of lowered vitality would be pointed out.

The circumstances attending the commencement of the disease would be investigated, and doubtless in this way considerable light would be thrown on its food relations. But, above all, the insanitary conditions which have been shown to bear such an intimate relation to phthisis, and which play a far more important part in the production of that malady than in any other infectious disease, would be investigated and removed precisely at the time when they were most dangerous both to the patient and to the other members of the family. On Oct. 24th and Nov. 7th, 1893, the subject was discussed by the Medical Society of Oldham. It was found that considerable hesitation existed with reference to the notification of tuberculosis, and that more particularly apprehensions were entertained that the sanitary officials would interfere between the medical attendant and his patients. No objections, however, were offered to a paper of instructions as to personal precautions being handed in by the sanitary inspector on which the medical attendant could enlarge. After full debate the members of the society agreed in recommending the voluntary notification of phthisis. It may be as well to recall the general position arrived at on that occasion, since it is, so far as I know, the only expression of opinion formulated by a body of general practitioners. The following notice of the meeting was given in THE LANCET of Nov. 18th, 1893:—

"OLDHAM MEDICAL SOCIETY.—On Oct. 24th a discussion on the subject of Notification of Phthisis was opened by Mr. Fawsitt, President of the Society, at a very full meeting. Several members took part in the discussion, and at the close of the meeting the subject was adjourned to another meeting, which was held on Nov. 7th. A number of speakers having expressed their views on the question, it was understood that

[1] Public Health, April, 1893.

Digitized by Google

the objects of notification would be: 1. The sanitary authority would disinfect the room occupied by the tuberculous patient, as might be required. 2. Inasmuch as the transmission of tuberculosis is in a large proportion of cases determined by the presence of insanitary conditions, such as damp, overcrowding, deficiency of light, and so forth, an opportunity would be afforded to the authority of removing such conditions and so saving other members of the household. 3. Further evidence would be collected bearing on the modes and conditions of transmission of the disease. 4. The personal hygiene of the patient would in no way come under the care of the sanitary authority; it was hoped, however, that the medical attendant would confer with the medical officer of health, when convenient, as to the precise means by which tuberculous discharges might be most usefully destroyed. At the same time the sanitary department would in no way interfere with the treatment of the patient, and all instructions in dealing with discharges from the patient would come from the medical attendant. 5. Only such cases would be reported as were taking place from the lungs, cases with tuberculous diarrhœa, and cases with copious discharge from tuberculous bones and tuberculous ulcers. These and other matters having been fully discussed, the following resolution was carried unanimously: 'That the society, having had its attention drawn to the infection of tuberculous diseases and to the great mortality and injury to the population arising therefrom, is of opinion that these diseases should be the subject of voluntary notification to the sanitary authority.' It was understood that a copy of the resolution would be sent to the sanitary committee of Oldham as well as to the medical journals."

Providing the fee of 2*s.* 6*d.* can be paid for each case reported, I do not object to voluntary notification being first tried, as it will give time practically to ascertain and deal with the difficulties of administration. At the same time it seems to me quite clear that, the connexion between insanitary conditions and the communication of phthisis being so close as it is, this alone would be a sufficient argument for compulsory notification, putting aside the other powerful reasons for it. Nor do I doubt that voluntary notification would speedily result in compulsory notification.

3. My third proposition was that Isolation Hospitals should be provided by sanitary authorities, jointly or separately, at the expense of the rates, for the isolation of cases of tuberculosis likely to cause infection. As it is, workhouse hospitals do at present provide a considerable amount of isolation for the very poor. But there are a vast number of artizan families which would decline to avail themselves of that refuge, and where the patient is a danger and a burden. I feel quite sure from the conversations I have had in the course of my inquiries that the provision of good hospital isolation would be hailed as a blessing by these poor struggling people, and it would be the means of removing infection from the home. Not only so, but those treated in the hospital for a time would be thoroughly indoctrinated with the measures of precaution taken, which would become part of their daily habit. They would therefore, on their return, be centres for the diffusion of knowledge on the subject. It is in the later stages of the disease that infection is most likely to occur and that the disease is most burdensome. This is precisely the stage which is not dealt with in convalescent homes, and which should be dealt with in the interests of public health. This proposal is, however, not necessary to the success of the first two.

4. Tuberculosis in cattle should be brought under the Contagious Diseases (Animals) Acts, and special veterinary inspectors should be appointed by sanitary authorities, singly or jointly, to carry out the objects of the Acts in relation to tuberculosis and other diseases, and to attend to the general sanitary arrangements of the cowsheds. I may be allowed to quote the continuation: "The officer to be appointed should be a young veterinary surgeon, well versed in the diagnosis of disease. He should receive a sufficient salary and travelling expenses. His duties should be something like the following. Once a month he should inspect the farm-buildings and note any conditions found on these or on the farms likely to act injuriously on the health of the cattle or on the quality of the milk He should examine the cattle and ascertain whether they were suffering from any disease. If he saw reason to suspect tuberculosis he should take measures to have the suspected animal isolated, and see that necessary measures of disinfection were carried out. The sale of milk from this animal would be stopped. If his diagnosis was clear and unhesitating the cow should be killed. Compensation should be given, the amount paid to have regard to the condition of the animal. In advanced tuberculosis it would be trifling—in an early stage of the disease such as would not entail any loss to the farmer. It would thus be to the farmer's interest to have such cases reported as soon as possible. Notification would be compulsory on the farmer. Constant practice in diagnosis would soon enable a good veterinary surgeon to have an almost instinctive knowledge of what he was dealing with, unless in very obscure cases. It is so in human diseases. The veterinary surgeon would also deal with the sanitary requirements of the cowsheds. Ordinary insanitary conditions about farms would be attended to by the inspector. I throw out these details merely by way of showing that the veterinary inspector would have enough to do. Having made his investigations, the veterinary inspector would report to the medical officer of health of the district, so that he might be able to coöperate with the veterinary inspector in getting the necessary preventive measures carried out."

I have already mentioned how in all probability tuberculosis is directly communicated in cowsheds from tuberculous cows. But, apart altogether from tuberculosis, the condition of our cowsheds and their relation to the public health through the milk supply demand investigation and rearrangement. It would be of great advantage if the regulations applicable to cowsheds were made uniform, so that any local action taken to improve their condition should not have the effect of transferring the milk-supply to another district perhaps as badly off in the matter of cowsheds as that in which the action was taken.

Oldham.

PERFORATION OF UTERUS BY SOUND OR CURETTE.

BY LAWSON TAIT, F.R.C.S. ENG.,

CONSULTING SURGEON TO THE HOSPITALS FOR WOMEN AT BIRMINGHAM, NOTTINGHAM, AND SOUTHAMPTON.

THE article by my friend, Dr. Auvard, in the *Archives de Tocologie et de Gynécologie*, noted in THE LANCET of Sept. 22nd, 1894, has been lying for months on my desk waiting the leisure the holiday season has given me that I might draw further attention to an interesting occurrence, long ago familiar, but apparently forgotten. When Simpson made the uterine sound practicable, he put it in the hands of every one, and its routine use did a great deal of mischief. Now it is relegated to its proper position, and used only in a very limited area of special practice. We do not, therefore, see now the cases of perforation of the uterus by the sound which were so familiar to Simpson's pupils and followers. In the columns of THE LANCET[1] I recorded my own first experience of it, stating at the same time the fact that it was well known to Simpson, whom I had often seen demonstrate it. Next month[2] Mr. Walter Whitehead recorded a case as having happened to Foltz and Petrequin, and narrated by the former before the Lyons Medical Society, where a female catheter, used for the purpose of inducing premature labour, passed through the fundus and was extracted through the umbilicus eighteen weeks after without any bad symptoms. Mr. Whitehead also mentions a fatal case in the experience of a friend. It would be a valuable contribution to the literature of the subject to have an account of this case, as it is the only disaster of the kind I have ever heard of amongst a number of perforations which I have seen and heard of, so great that I should be afraid even to attempt to guess at the total. It must be strictly borne in mind that all the cases of which I speak occurred in the non-pregnant uterus.

Dupuy collected seventeen cases,[3] in none of which did any subsequent evil effects arise. Commenting on this paper Dr. W. S. Playfair said that it was probable that in many of these cases the sound passed through the Fallopian tubes. This point used to be one of periodic discussion between the late Dr. Matthews Duncan and myself, and I can accept the view shared by him and Dr. Playfair still less now than in the time of those discussions. It is fashionable now to talk of passing sounds and catheters through the Fallopian tubes (and ureters). I have tried on the cadaver, but (though fairly nimble with my fingers) I have never succeeded, and I have never seen anyone else succeed, though I am far from saying that such passage is an impossibility. Again, I have seen as many pathological

Digitized by Google

tubes as I suppose any other living person, but I never saw a tube in which abnormal patency was a feature. I certainly never saw a normal Fallopian tube—I mean one not distinctly pathological—through which an ordinary uterine sound could be passed. But I have seen several uteri through which sounds could easily have been passed by reason of the thinning of the wall at the outward curve of a chronic flexion, or by the atrophy of the wall at the insertion of a small nodule of myoma. I have also seen two uteri through which the sound or curette actually had been passed, one at the time of an ovariotomy,[4] and the other recently in a uterus I removed by vaginal hysterectomy. I have also recorded three cases of what appeared to be cases of permanent metro-peritoneal fistula.[5] One of these cases possesses the fistula still, as I know the patient is alive, and I passed a sound at the old spot about three years ago. In making these observations we never sterilised the sounds, and now it amazes me, if peritonitis is caused by micro-organisms, why we never produced it.

The last case of instrumental perforation of the uterus with which I have met is one of great interest, for the patient had had her appendages removed for myoma some five years before by Mr. Knowsley Thornton with a brilliantly successful result—that is, all the symptoms and troubles due to the myoma disappeared, and she went through a brief and satisfactory climacteric. When I examined her I could find no trace of myoma. The patient had an idea, at the time of this operation that the uterus itself ought to have been removed, but of this I was finally able to dispossess her, for it seemed to be an ideal case for removal of the appendages, and the result all that could be wished. I mention this circumstance because she was placed under my care by a well-known Midland practitioner, whose name I do not give because with it the name of the patient might just as well be published. The reason of her coming to me was that for about eight months she had been troubled by an increasing purulent and very acrid discharge pouring out of the uterus. This discharge was extremely offensive, accompanied by pain and interrupted occasionally by hæmorrhages. It made her extremely miserable, and brought back to her mind somewhat bitterly her original desire to have the uterus removed and Mr. Thornton's refusal to comply with it. The remedy I suggested was, of course, the curette, though not without fear that the disease might be endometric ulcerative epithelioma (a very rare condition), and in consequence this might prove insufficient. Just as I had nearly completed the operation the curette went through the anterior wall of the uterus and I could feel its point easily through the abdominal wall. As usual, the accident did no harm; the patient recovered easily and for nine months remained quite well. She came back, however, later with all her symptoms renewed, indeed intensified, and begged me to remove the uterus. I was not much in favour of this proceeding, as I was by this time quite certain that the correct diagnosis was that of epithelioma, and I am not at all favourable to operations for cancer of any kind—I am quite sure that vaginal hysterectomy for *réal* cancer of the uterus will soon go out of fashion. I removed the uterus in this case, however, under the belief that if such a thing were justifiable at all in cancer it was in the rare endometric ulcerative epithelioma which is very like the epithelioma of the lip.

The operation was very difficult, on account of old adhesions, but it was through in about twenty minutes, and then I found a few nodules of myoma at the fundus of a perfectly senile uterus. They were not larger than marbles, and must have been the mere survivals of Mr. Thornton's tumour, as they were wholly unrecognisable before the excision of the uterus. On slitting up the organ I found no trace of epithelioma, but a merely rough and hypertrophied endometrium, quite tough and very vascular. At the base of one of the nodules on the anterior wall, where it was of almost paper thickness, was an unclosed rent, about half an inch across, which had been made by my curette, and the edges of which, but not its lower end, had healed. Here at last was the absolute proof of a permanent metro-peritoneal fistula, through which I have no doubt much of the discharge must have made its way, after its re-establishment, but there was no disturbance from the microbes.

CASE OF FŒTAL ENDOCARDITIS ASSOCIATED WITH AN ARREST OF DEVELOPMENT OF THE INTER-VENTRICULAR SEPTUM.[1]

BY T. C. RAILTON, M.D. LOND.,
PHYSICIAN TO THE MANCHESTER CLINICAL HOSPITAL.

A CHILD aged four years was admitted into the Manchester Clinical Hospital on Jan. 24th, 1895, suffering from broncho-pneumonia. His previous history was to the effect that he had always been a delicate child, did not walk until he was eighteen months old, and subsequently was unable to play about like other children, being easily exhausted and out of breath. He had frequently complained of pain in the region of the heart, but had not suffered from articular rheumatism or shown any blueness in the lips or fingers. Three weeks before his admission he caught cold and had gradually got worse, and when admitted he had well-marked symptoms of broncho-pneumonia, his respiration being 60, pulse 140, and temperature 101° F. The deep cardiac dulness extended upwards as high as the second rib, on the right side nearly to the nipple line, and the apex beat was in the sixth interspace outside the left nipple line. There was no murmur audible. The patient became steadily worse, the temperature continued to rise, at one time reaching as high as 106·2°, and he died twenty-seven days after admission. Four days previous to his death a systolic murmur was audible over the right ventricle for the first time.

At the post-mortem examination both lower lobes were found consolidated, sinking in water, while islets of broncho-pneumonia were scattered over the rest of the lungs. The pericardium contained about two drachms of clear fluid. The heart was very large, mainly upon the right side. The thickness of the wall of the right ventricle was eight millimetres, of the auricle one millimetre. The corresponding measurements of the left side were nine millimetres and one millimetre respectively. The tricuspid valve was the seat of large verrucose vegetations covered with a deposit of fibrin. Close to the tricuspid orifice were a few other vegetations on the auricular edge and one recent irregular ulcer. The remaining orifices and valves were normal, and the ductus arteriosus and foramen ovale were closed. There was a deficiency of the septum of the ventricles about the undefended space large enough to admit a quill. This opening was larger at the side of the left ventricle than on the right side, where it ended between the insertion of two cusps of the tricuspid valve nearer to the right auricle than to the ventricle. The edges of this orifice were quite smooth. It was evident that the lesion of the tricuspid valve had started during fœtal life, and it seemed almost equally clear that the endocarditis had also continued its evolution subsequently to birth. A similar case has been reported by Dr. F. Robinson.[2] A child eighteen months old had suffered from palpitation and dyspnœa since birth. He was not cyanosed. There was a loud sawing murmur accompanying the heart's action. At the necropsy the right ventricle was found to be large enough to contain a hen's egg, and the tricuspid valve was thickened at its free border to such an extent as to prevent its perfect closure. There was also a circular orifice almost as large as the little finger in the septum of the ventricles communicating between the two cavities. The foramen ovale was closed and there were no remains of the ductus arteriosus.

Although the valvular disease of my own case was due to endocarditis, the opening in the septum can hardly be ascribed to the same cause. The edges were smooth and bore no trace of inflammation, and, in fact, the opening exactly resembled those cases of defective development in which there is no evidence of endocarditis in any part of the heart. The question naturally arises as to the possible connexion, if any, between the arrest of development and the endocarditis in this and Dr. Robinson's case. I am inclined to believe that in my own case the defect in the septum may have been the

[1] Communication made to the Pathological Society of Manchester, April 10th, 1895.
[2] THE LANCET, July 22nd, 1848.

Digitized by Google

cause of the endocarditis. It is evident from the formation of the opening in the septum that the stream of blood would pour during systole from the left side to the right, and it is conceivable that the impact upon the tricuspid valve may thus have given rise to the endocarditis. It would be difficult to ascribe the arrest of development in the septum to the endocarditis and subsequent incompetence of the tricuspid valve, as that theory would entail our dating back the endocarditis to a period anterior to the third month of fœtal life; and moreover, had increased pressure within the right ventricle prevented the completion of the septum, one would naturally look for the opening to be larger upon the right side than upon the left.

Manchester.

SOME REMARKS ON TYPHOID FEVER MADE AT A CLINICAL DEMONSTRATION IN THE WARDS OF THE ROYAL BERKSHIRE HOSPITAL, READING.[1]

BY FRANCIS HAWKINS, M.B. EDIN.,
PHYSICIAN TO THE HOSPITAL.

THE patient was a man twenty-seven years of age who had been a scavenger. When admitted to hospital on June 11th he said that he had had slight diarrhœa on the first day of the month, but continued at his work until the fifth, when he had a shivering fit, and owing to the diarrhœa increasing took to bed. When I saw the case on the eleventh day, shortly after his admission, the house physician took from my dictation the following notes: "The patient complains of frontal headache and diarrhœa. He lies on his back. The face is markedly flushed and his pupils are dilated; his tongue is beefy red, moist towards the edges, but dry at the centre. The abdomen is tumid, tympanitic over all regions, but markedly so over the colon. Two circular pink spots, slightly raised from the surface and disappearing on pressure, are seen in the left umbilical region. The spleen is enlarged upwards, the lower border not being felt; the liver is not enlarged; the heart is normal. There are a few sibilant râles at the base of both lungs. There is no albumen in the specimen of urine examined; the temperature is 102° F." Since admission there have been several successive crops of spots. The temperature has, with one exception, not been above 102°. The bowels, however, have been frequently and profusely active. In addition to this, on the sixteenth day at 4.30 A.M. about one pint of blood, dark in colour and somewhat clotty, was passed, and a similar quantity again at 7.30 A.M. There was no sign whatever of collapse (the temperature, however, which had previously risen a few degrees, fell from 102·6 to 99·2). I wish to refer in this place parenthetically to the occurrence of typhoid fever at various periods of life. While it is most common during the second and third decades, yet it is very prevalent during the first, but it is not by any means common before the second year of life. I have myself never met with a case in a patient under two years and a half old, but Meigs and Pepper record a case as young as one year and six months. In the cases from which my own investigations have been made not one was under two years. Henoch in 256 cases also found none under two years. This fever may in exceptional instances be met with at an advanced age. One case recorded within my knowledge occurred between the ages of seventy and eighty—the exact age was seventy-six. The most advanced age of which I find an account was a case mentioned by Griesinger as having been observed by Hammernyk when the patient was ninety years of age.

[Dr. Hawkins here quoted statistics showing that typhoid fever is most prevalent during the months of August, September, October, November, December, and least prevalent during April, May, June, and July. He proceeded:]

The eruption in this case appeared first on the day of admission. I have it from the previous medical attendant that none was to be seen on the day before admission, but on the day of admission—the eleventh day of illness—two spots were seen. The typical typhoid eruption is not present in every case; it is, however, more frequently present than absent. As regards adults, it is more frequently present in the male than in the female, being seldom absent in the male. In children it is less frequently present than in the adult. In male children it is almost as frequently absent as present, but in females it is more frequently present than absent.

The date of the appearance of the eruption is worthy of notice. In this case it appeared on the eleventh day. Murchison tells us that the spots appear between the seventh and twelfth days inclusive. In an investigation made by him it was so in 39 out of 46 cases; in 4 only were the spots seen before the sixth day, and that was on the fifth; and in 3 cases the spots were not seen till the fourteenth, and in one case not till the twentieth day. Murchison, however, made no distinction between the date of appearance of the eruption in children and in adults, and as this line of inquiry seems to be of interest and importance I will give some of the results of my investigation. I find that the eruption may appear earlier in children than in adults; thus in the former (of 78 cases) the eruption appeared on the third day in 1 case and on the fourth day in 3 cases. In the latter (adults) in 69 cases the eruption did not appear in one single instance before the fifth day. In 2 cases which I have lately seen the eruption did not appear till the eighteenth day.

The situation of the eruption is almost universally on the abdomen. Among 56 cases where its distribution was particularly noted, in one case only was the eruption absent from the abdomen, and in that instance it was on the chest and back. It is, however, to be remembered that while the eruption is so constantly present on the abdomen it may appear in other parts as well. Thus it may be on the back, chest, between the thighs, on the knees, shoulders, elbows, forearm, neck, and face. It may be very profuse or very scanty. Shortly before leaving London I saw in consultation a case in which the eruption was so general and so widely distributed that the practitioner in attendance thought it of an influenza type. There are other conditions of the skin which must be mentioned, for in addition to sweating and the presence of sudamina there may be erythema, eczema (which is perhaps the least common of any one case out of 240 presenting this condition), urticaria, herpes facialis, and labialis. Abscesses also appear as alveolar, parotid, or on the hips. It must, however, be mentioned that with the exception of erythema the majority of the above-mentioned are met with as sequelæ. And this reminds me of one case I saw while resident physician in the Royal Infirmary at Edinburgh, in which, during convalescence, an abscess formed at the ankle joint, and the os calcis was found to be so much necrosed that the foot was amputated. Previously to the fever no sign of any such condition was present. Boils also may appear: in the experience of some they are of frequent occurrence. The eruption of measles, as also the rash of scarlet fever, may arise during the course of the disease. Desquamation of the skin apart from this cause may also be met with. It was noticed in 11 out of 240 cases, the earliest appearance being on the twentieth day and the latest the thirty-eighth. "Purpura may occur," Fagge says, "in typhoid cases with hæmorrhage from the bowels"; but in 61 cases of hæmorrhage from the bowels (representing a ten years' experience at the Middlesex Hospital) purpura did not occur in one single case. Purpura rheumatica claims two instances. One, a man aged twenty-two years, who had previously suffered from rheumatic fever and hæmoptysis, and in whom a cardiac bruit was present, had on his admission both legs from the knees downward studded with minute petechiæ, and on both ankles and on the dorsum of each foot large hæmorrhagic plaques. For some time the case was regarded as one of peliosis rheumatica. On the sixteenth day typical typhoid spots appeared, and on the twenty-second and twenty-fifth days crops of spots appeared "which became petechial." The other case was a man fifty-two years of age who had petechiæ over the ankles. Both cases recovered. I call special attention to the expression "became petechial," because Murchison says: "When petechiæ occur they are not developed in the centre of the ventricular spots, but are independent." The above case was not seen by myself; it is recorded in the published reports of the Middlesex Hospital, and was noted by such a competent observer as Dr. J. J. Pringle, who was registrar at the time.

[1] I must publicly tender my thanks to the staff of the Middlesex Hospital for their kindness in having placed at my disposal the notes on cases of typhoid fever for the past ten years, whence all my facts not otherwise stated have been drawn.

[Dr. Hawkins here referred further to the comparative rarity of purpura in typhoid fever. He continued:]

I now come to the condition of the bowels and the frequency of the stools. This is one of the difficulties with which we have most to contend. The notes of the case mentioned the presence of tympanitis over the regions of the colon, indicating distension of that part of the bowel. Now in several other cases in which I have detected this condition, which is nearly always associated with profuse diarrhœa, extensive ulceration of the colon has been found at the necropsy. Diarrhœa is the rule in typhoid fever, constipation the exception; but it must also be remembered that there may be diarrhœa for a few days—say, the first five or six—followed for one or two weeks by the most obstinate constipation, demanding enemata for its relief. This latter condition is much more common than constipation throughout. The bowels may be moved from twice to twelve or more times in the twenty-four hours. In addition to frequency of the stools we have here had to contend with hæmorrhage from the bowels, and this symptom demands more than passing attention. Graves was the first to teach that hæmorrhage from the bowels in typhoid fever might be a favourable symptom rather than an unfavourable—he regarded it "as a wise provision of nature which might usher in a favourable crisis, but as an occasional result it was of great danger." Trousseau for some time held that it was a formidable symptom and increased the danger, but after reading Graves' lectures he changed his opinion and stated "that as a symptom intestinal hæmorrhage did not possess the dangerous character imputed to it, but that it was usually of a favourable augury." Sir William Jenner writes: "Hæmorrhage from the bowels is a very grave symptom, but it is by no means necessarily fatal." And Sir William Broadbent, writing in Quain's Dictionary of Medicine, tells us that, while intestinal hæmorrhage is a symptom which causes anxiety, it is by no means necessarily fatal. Murchison regarded it as a very formidable symptom, but Habershon wrote: "It is in my experience rarely fatal." Some time ago I made an investigation relative to this important symptom with the object of finding some basis for forecasting the issue of cases associated with it. A glance at this tabular statement will show that up to the age of twenty more cases recover than die, and that between twenty and twenty-five nearly as many cases die as recover, but that between twenty-five and thirty more recover than die. After the age of thirty more die than recover. We have, therefore, so far as age is concerned, some data for making a prognosis, for, speaking broadly, one may say that up to the age of twenty the symptom is less indicative of danger than it is after that age. In non-fatal cases hæmorrhage usually occurs but once—that is to say, only at one period is blood seen in the stools, and it may vary from a few streaks to one pint. A single hæmorrhage occurred in seventeen out of twenty-eight non-fatal cases. Hæmorrhages in fatal cases are more frequently recurring. Of twenty-four fatal cases there were but three instances of a "single occurrence"; but when these recurrent hæmorrhages are fatal we have no data to guide us, for in both fatal and non-fatal cases the recurrences may be equal in number and frequency. Hæmorrhage associated with perforation is always fatal, and is more frequently recurrent. When a hæmorrhage of the single type has occurred comparatively early in the course of the fever, and for a while the patient seems to have passed the danger point, hæmorrhage of the recurrent type may occur later, from which the patient dies. With regard to the time of the occurrence of the hæmorrhage there is practically no difference. I must lay stress upon this, for many persons think that hæmorrhage early in the course of the fever is not fatal. So far as my own observations go, data of this kind are not reliable, neither does the quantity of the blood passed help much in guiding our judgment, for in non-fatal as well as in fatal cases the quantity may be large or small, and we must further remember that, while the quantity passed by the bowel may be small, a large quantity may remain in the intestine.

Tabular Statement of Ages at which Hæmorrhage from the Bowels occurred in Typhoid Fever, showing the Ages of Non-fatal and Fatal Cases.

I must be brief as to treatment. The patient was at first put on a purely milk diet, but shortly afterwards he vomited curdled milk, and in the stools there was also undigested milk. This form of diet was therefore stopped, broths being given, and during the time of the hæmorrhage raw meat juice. Milk, if a patient can digest it, is by far the best diet, yet it should not be unduly pushed when, as in this case, there is evidence that it does not agree. In fact, it may do harm not only by causing sickness, but also by increasing the diarrhœa. For checking activity of the bowels I prescribed bismuth and compound powder of ipecacuanha. However, I am bound to admit it has not answered my expectations. Starch and opium enemata were then ordered, but as this did not check the activity of the bowels I ordered opium by the mouth in addition; by this combination I succeeded in diminishing the frequency of the stools. During the attack of hæmorrhage, in addition to slightly increasing the dose of opium an icebag was placed over the abdomen, and more especially over the right iliac region, suspended from a cradle so as to touch the abdomen lightly and to be removed at intervals. The hæmorrhage eventually ceased. In some instances the cold pack is of great use, but in this case the temperature had never been higher than 102° and therefore in my opinion did not require any special treatment. Stimulants were not administered at first, but a few days after admission the pulse became not only irregular, but also intermittent, and brandy was therefore given. So soon as the desired result was obtained it was stopped, but latterly it has been given regularly because there are indications of cardiac failure.

A CASE OF TETANUS TREATED WITH TETANO-ANTITOXIN, AND A REVIEW OF THIRTY-EIGHT OTHERS.

BY F. HERBERT MARSON, M.D. DURH., F.R.C.S. ENG.,
LATE HOUSE SURGEON TO THE STAFFORDSHIRE GENERAL INFIRMARY.

I HAVE to thank Mr. Weston, senior surgeon to the institution, for permission to publish the following case.

On Nov. 10th, 1894, a man aged twenty-eight was admitted to the Staffordshire General Infirmary with a compound fracture of the first phalanx of the left thumb, and complaining of slight stiffness of the masseter muscles. The injury to the thumb, which was slight, had been received ten days previously and had been medically treated from the first. The stiffness of the jaws had only commenced on the morning of his admission. The patient was a strong, healthy man. His pulse and temperature were normal. There was slight stiffness of the jaws. The wound, which was small, did not look healthy. He was put on five grains of quinine every four hours and a quarter of a grain of extract of physostigmine hypodermically every six hours. On the 13th his condition remained practically the same; the pulse was normal and the temperature never exceeded 99·4° F. He could open his mouth about half an inch. As the wound still looked unhealthy the thumb was removed. On the 14th, on account of the cardiac

Digitized by Google

depression that the physostigmine was supposed to be causing, chloral and bromide of potassium were substituted. On the 15th physostigmine was recommenced. During the last three days the condition had remained unchanged, with the exception that there had been very slight twitchings of the muscles of the left arm and the side occasionally, and the stiffness had extended to the muscles of the neck. On the 16th the physostigmine was stopped. The pulse was normal and the temperature had been subnormal from the 13th up to this date. At 11 A.M. there was a slight spasm, which was principally confined to the diaphragm and the muscles of the larynx, and only slightly affected the muscles of the legs and back; at 12.30 thirty-four grains of tetano-antitoxin were injected, to the strength of one grain to eleven minims of water; this was injected at two points in each extremity without an anæsthetic, the needle and syringe having been previously sterilised. At 8.30 P.M. the temperature was 101·6° and the pulse 132. The patient seemed better; the cervical muscles were less hard, and he could open his mouth wider and put his tongue out slightly. Antitoxin (thirty-four grains) was re-injected. From the 16th until the termination of the case the pulse, which had previously been normal, rose, and oscillated between 116 and 152. On the 17th the temperature was 98·4° and the pulse 120. There was a rather severe paroxysm of convulsions threatening asphyxia by spasm of the glottis. At 8 P.M. there had been no recurrence of the spasms. The patient was more cheerful, the muscles of the neck were softer, and he could open his mouth better. Antitoxin (twenty-eight grains) was injected. On the 18th, as the spasms were much better and the muscles softer, it was decided to reduce the dose of antitoxin. Injections of the latter (eight grains) were given at noon and at 8.30 P.M. On the 19th the temperature was 98·2° and the pulse 120. There had only been two slight spasms during the last twenty-four hours. He was much better in himself and expressed a strong desire for a pipe. Antitoxin injections (eight grains) were given at noon and at 8.30 P.M. On the 20th the patient felt better and looked bright. Antitoxin (eight grains) was injected at 8 A.M. The temperature rose to 103°; there were no spasms. On the 21st, as the spasms had ceased and the muscles of mastication were more relaxed, the antitoxin was discontinued and five grains of quinine three times daily were ordered. The temperature in the evening was 103°. On the 22nd the temperature was still 103° in the evening; the patient was rather restless, but quieted down on being given bromide of potassium. On the 23rd the temperature was still 103°. The patient did not know anybody, tossed about, and was delirious. There were symptoms of commencing endocarditis. On the 24th he was better; there was no delirium, but the temperature was still 103°. He was now in a typhoid condition. On the 25th the temperature was 104·2° and the pulse 128. He was sinking. On the 26th the temperature was persistently high. The heart was very weak and the pulse running. He was ordered tincture of digitalis and carbonate of ammonia. At 11 P.M. there were gasping respirations. He died on the 27th.

Remarks.—No necropsy was allowed. During the whole time he took his nourishment well, which consisted of a liberal allowance of milk, eggs, meat essence, and brandy in addition to tonic drug treatment. All the injections were given without an anæsthetic for the following reason. On giving the anæsthetic (ether) for the removal of the thumb the patient after a few inhalations became blue and ceased to breathe; prompt measures for resuscitation were employed, and he subsequently recommenced breathing. The probable explanation is that the tongue lolled back over the larynx, as the heart continued to beat although the breathing had ceased; the rigidity of the jaws prevented the mouth being opened. I mention this circumstance, as the injections are recommended to be given under an anæsthetic, and it is a condition that is not unlikely to happen again, and, may be, with a less favourable result. As many recorders of such cases note, it is impossible to draw reliable deductions from an isolated case, and I would make the same observation regarding this one. As the cases in which this new treatment has been tried are relatively few, I think it equally important that the unsuccessful as well as the successful ones should be reported. Taking this case alone, I should be inclined to draw many unfavourable deductions. It was undoubtedly a case of a very mild type. There appears to be no doubt that the antitoxin injections did have a marked beneficial effect on the rigidity and general condition; this appeared a few hours after the first injection, and, so far as the spasms and rigidity were concerned, the benefit was permanent. There is one point I wish to draw particular attention to—viz., that in the opinion of the surgical staff the man died from septicæmia. The thumb was removed soon after his admission; although not healing by first intention, it took on a healthier tone, and never at any time subsequent was the appearance such as would account for the septicæmic condition. Every possible antiseptic precaution was taken; the hypodermic needles, &c., were carefully sterilised by boiling, and for a considerable time the hand was kept in a carbolic bath. The inference naturally arises, Did the septicæmia, if such he died from, have any connexion with the antitoxin injections? Upon this point it is impossible to speak positively; not a single recorder hints at such a source of death after injection. Against this supposition it is only right to mention that, with the exception of a slight temporary elevation after the first injection, the temperature remained normal for five days, during which time two injections were given daily. In spite of the unfavourable termination, and bearing in mind that it is only a single case, that a condition arose that has not been noted by any other observer, that it is possible it may have had no connexion with the antitoxin, and that apparently brilliant results have arisen in the practice of independent and unbiased observers, I should be very loth to condemn the treatment for one unfavourable termination.

I may say I have collected all the procurable published and unpublished cases of tetanus treated by antitoxin up to the present time, numbering thirty-eight, which show the following results. But I would point out that, in reviewing the mortality statistics in this disease, there appears to be some considerable difference of opinion, this arising in a great measure from some writers describing the disease as occurring both as an acute and chronic affection, whilst others seldom or never recognise it as occurring in a chronic state. The following analysis gives the number of recoveries and deaths of the cases treated with antitoxin:—

—	Recoveries.	Deaths.
Total number of cases collected, 38, including cases that are only mentioned as having been treated, no further particulars being given	25	13
Number of cases treated of which particulars are given, 22	17	5
Number of cases treated, of which particulars are given and which were regarded by their recorders as "severe," 9	5	4
Ditto, "not severe," 13	12	1

I think the average mortality of tetanus in chronic cases may be regarded as 50 per cent., and in acute or severe cases as 90 per cent. I have arranged in the four following groups all the recorded cases of treatment of tetanus by immunised serum. Of the 38 cases collected, only 22 were fully reported; they fall under their respective heads as follows: (1) Cases in which the symptoms commenced to abate immediately after injection and then steadily disappeared, 9; (2) those which remained *in statu quo* for a short time after injection and then gradually improved, 6; (3) those in which no further muscles became involved in spasms after commencement of treatment, though occasionally an aggravation of certain other symptoms (as trismus and difficulty in swallowing) occurred, 2; and (4) those ending fatally notwithstanding treatment, 5. Space does not permit of a detailed notice of the cases, but in spite of the unfavourable result of the case treated in the Staffordshire General Infirmary I have come to the following conclusion. In my mind there is no doubt that the antitoxic serum has a favourable effect in certain cases of tetanus, and those not always of the mildest form. This serum may be justly called a remedy for the disease of such importance that up to the present time no other method of treatment can bear comparison with it. I am of opinion that the antitoxin serum is destined considerably to decrease the mortality in tetanic cases, and I do not doubt—although there is probably much to be learned and many details have to be modified or altered—that the hopes raised by it will be fulfilled.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A RARE CONDITION OF THE OMENTUM.

BY J. GREIG SMITH, M.B., C.M. ABERD., F.R.S. EDIN.,
SURGEON TO THE BRISTOL ROYAL INFIRMARY.

AT an operation for the removal of a solid pelvic tumour performed on May 5th of this year a condition of the omentum was found which I have endeavoured to show in the accompanying sketch, life-size. On completion of the parietal incision, which was carried above the umbilicus, there protruded coils of vessels which exactly, in colour and size, resembled fat, well-developed earth-worms. They were hard, tense, and glistening, and looked so like worms that for a moment I was nonplussed, nor could my experienced assistant, Mr. Swain, or Dr. Michell Clarke, under whose care the patient was, suggest what they were. Prolongation of the incision upwards and a more close examination at once showed that they were the vessels of

the omentum. Here and there small tags of areolar tissue containing a little fat could be found on the vessels; but the whole omentum was transformed into a network of large vessels without any fat. A good many of the vessels were closely adherent to the tumour, these were tied in a bunch and divided. The rest of the omentum was left intact. The whole surface of the tumour was very vascular, and could not be handled without causing free bleeding. In spite of rapid delivery and the free use of large pressure forceps a great quantity of blood was lost before any tissue was divided. The bladder was embedded in the tumour, and its adhesions were more vascular than I have ever seen. The patient, a lady aged forty, had suffered severe pains for several years during the growth of the tumour, and was very thin. She made an excellent recovery. The exact nature of the growth has not been made out, probably it will turn out to be a myoma with sarcomatous elements.

Bristol.

FRACTURE OF THE CORONOID PROCESS.

BY R. S. CHARSLEY, L.R.C.P. LOND., M.R.C.S. ENG.

A GIRL aged twenty was thrown out of a dog-cart through the wheel coming in contact with a large stone at the corner of a street. I saw her an hour after the accident. She told me she had stretched out her arm to save herself and had fallen with all her weight on her hand. I found the right hand bruised and cut by the stones. The right elbow was very painful and I was for some time puzzled to account for the pain, all the bony prominences being uninjured and in place, the radius rotating freely, and the movements of the elbow joint being perfect, although accompanied by much pain. Pain was also produced by pressure on the head of the radius. I found, however, that when I grasped the lower end of the humerus in one hand and the fore-arm in the other, the latter being brought to a right angle with the former, a very slight amount of backward pressure produced a backward dislocation of the joint, the olecranon projecting considerably behind the humerus, and that when the pressure was reversed the joint slipped back into its place with the greatest ease. This proceeding I repeated once or twice, the dislocation being produced and reduced without the least difficulty. I placed a small roll of wool in the bend of the joint and secured it with a bandage round the joint and then put the arm in plaster of Paris with the elbow flexed till the bandage became fairly tight. In three weeks I commenced passive movement and obtained in the end a completely satisfactory result. I cannot account for these symptoms except by supposing that the coronoid process had become separated from the ulna by the fall on the outstretched hand. The great rarity of the accident makes the case worth recording.

Slough.

A CASE OF RAYNAUD'S DISEASE.

BY BRIGADE-SURGEON-LIEUTENANT-COLONEL E. J. FAIRLAND,
ASSISTANT PROFESSOR OF MILITARY MEDICINE, ARMY MEDICAL SCHOOL, NETLEY.

A MAN aged twenty-five was admitted to the Royal Victoria Hospital, Netley, on Jan. 19th, 1895. He was invalided from Hong-Kong for malarial cachexia. He had served in China for three years, enjoying fairly good health except for frequent attacks of ague, accompanied by coldness and numbness of his extremities. On the voyage home a bluish discolouration of the lobe of the left ear was noticed, and his hands and feet became benumbed and very painful. On admission he was in a very cachetic state; the hands and feet were in a condition of extreme venous engorgement, œdematous, and of a purplish colour. This cyanosis implicated especially the toes and forepart of the right foot, the index and middle fingers of the left hand. The point of the nose, the lobe of the left ear, the left thumb and left great toe also became cyanosed; and at times the right ear was similarly affected. The discolouration of the ears and nose was of a recurrent character, frequently disappearing altogether. Anæsthesia existed in the affected parts, and for some distance above them. At first, however, intense pain was felt in the regions above the cyanosed parts. Gradually the œdema subsided, the livid marbling of the surface disappeared, and early in February half of the right foot, the plantar surface of the left great toe, and the index and middle fingers of the left hand became mummified, shrivelled, and black. A line of demarcation formed above the gangrened portion of the right foot, accompanied by a fœtid discharge; but Nature made no effort elsewhere to throw off the diseased parts. Throughout the attack the pulse remained small and feeble; the temperature ranged between 97° and 101°F. The spleen was enlarged and tender. The other organs were normal. The urine was non-albuminous. On April 13th Surgeon-Colonel W. F. Stevenson removed the right foot (Syme's amputation) and the diseased fingers. The patient made an excellent recovery. Exposure at sea was the direct cause of the attack. Ague is a recognised factor in its etiology, and the patient's constitutional tendency to a stasis of the peripheral circulation was increased by his cachectic condition, which produced the lowered tissue vitality essential to the disease. Raynaud's three stages of local syncope, local asphyxia, and symmetrical gangrene were well marked; the case was characteristic in its etiology, progress, and result. The treatment was based on the symptoms—opium to relieve pain, and quinine and generous diet to remove the cachexia. The case was under the care of Surgeon-Lieutenant-Colonel H. H. Stokes, A.M.S.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

OTORRHŒA; LATERAL SINUS THROMBOSIS; OPERATION; RECOVERY.

(Under the care of Mr. BERNARD PITTS.)

THIS is another instance of successful operation for septic thrombosis of the lateral sinus due to disease of the middle ear. As time goes on the great importance of the symptoms of this condition will be recognised, and we may hope that the patient will be sent up for operation at an earlier date rather than when his state is almost desperate. It is a subject for surprise as well as congratulation that this patient recovered. The symptoms of septic thrombosis of the lateral sinus are generally well known, but vary to some extent in different cases. The occurrence of pain over the mastoid process, vomiting, rigors, high and irregular temperatures, and the history of a chronic discharge from the ear should always make the medical attendant suspect the presence of a septic thrombosis of the sinus. In this case there appears to have been no swelling or tenderness along the course of the internal jugular vein in the neck, a symptom rightly regarded as a very important one, and we note the presence of internal strabismus. This was probably of old standing and not due to any meningeal inflammation of recent origin. We think, however, that a statement with regard to this would have been advisable as great difficulty is sometimes experienced in diagnosing an obscure case of thrombosis from one of tuberculous meningitis, and the presence of a recent strabismus is regarded as a strong argument in favour of the latter. The formation of deep abscess in the neck after operation takes place usually in one of two ways, either as the result of the escape of the pus of a suppurating thrombus through the wall of the portion of vein between the ligature in the neck and the lateral sinus or by the spread of pus along the surface of the internal jugular vein in those cases where it had previously formed in the sulcus lateralis. For the notes of this case we are indebted to Mr. Gerald Baldwin, surgical registrar.

A boy aged nine was admitted into the Hospital for Sick Children, Great Ormond-street, on March 23rd of this year. There was a history of twelve months' offensive discharge from the right ear. He had been treated for eight weeks at a special hospital and the discharge had ceased; but on March 14th he complained of intense ear-ache and frontal pain. On the 22nd the discharge from his ear began again after the application of poultices over the mastoid bone. On the morning of the 23rd he became delirious. When admitted he was very ill, with the temperature 103° F., the pulse 140, and the respiration 40. He complained of frontal headache, with pain and tenderness behind the right ear. Over the right mastoid process fluctuation was felt. Internal strabismus was noted in the left eye, and the ophthalmoscope showed blurring of the left optic disc with enlargement and tortuosity of the retinal vessels. The right disc was normal. Mr. Pitts saw the case in the afternoon and decided on immediate operation. An incision behind the right ear set free a small quantity of pus. The mastoid antrum was opened with a gouge and was scraped out together with the tympanum. Finally, the lateral sinus was freely exposed. After this had been done some very offensive pus oozed out from behind the sinus. Puncture of the sinus with a tenotomy knife revealed the presence of purulent clot in its interior. This was removed after incision. The immediate effect of the operation was a fall of temperature to 99°, but next morning the glass registered 104°. On the 25th Mr. Pitts tied the internal jugular vein at the level of the cricoid cartilage, the vessel being collapsed and empty. Even after this progress towards recovery was very slow and broken by rigors on four occasions, with high temperatures reaching at one time 106°. Two large and deep-seated abscesses formed in the neck, one around the internal jugular vein, the result of septic phlebitis, and the other below the right mastoid process, due to direct infection. These required incisions and drainage. The general treatment adopted was mainly dietetic and stimulant, the boy being encouraged to eat what he most fancied. All the wounds healed satisfactorily, though slowly, and he was allowed out of bed on May 17th, and sent to the convalescent home on June 3rd. He was then perfectly well, though naturally weak after so severe an illness. There was a slight discharge from the right ear and from the mastoid wound. The temperature had remained normal for four weeks. Both eyes were normal.

Remarks by Mr. BALDWIN.—The successful result of this case shows how hopeful we may be of success in lateral thrombosis provided the treatment be sufficiently thorough. At one time the patient's chance of recovery appeared to be very slight, but by energetic surgical treatment, with stimulation and good nursing, his life was saved. The condition of the patient when admitted, together with the rigors and remittent temperature persisting after operation, appear to show that even before admission he had absorbed a considerable quantity of the septic products into the general system, and his recovery is therefore all the more satisfactory.

Reviews and Notices of Books.

A System of Surgery. Edited by FREDERICK TREVES, F.R.C.S., Surgeon to the London Hospital. Vol. I. With two coloured plates and 463 illustrations. London, Paris, and Melbourne: Cassell and Company, Limited. 1895.

[SECOND NOTICE.]

THE articles on Injuries of Bloodvessels, Diseases of Bloodvessels, and Aneurysms are written by Mr. Pearce Gould. They are noticeable for the systematic plan on which the subjects are dealt with, as well as for the scientific spirit that pervades them. The important matter of Hæmorrhage and its arrest is discussed in a manner that is worthy of attention, showing that the author has bestowed much thought upon it. Thus, he defines secondary hæmorrhage as "bleeding arising from failure in the repair of an injured or ligatured vessel, or from ulceration into a vessel," a definition which embraces all the multifarious causes that may give rise to this variety of hæmorrhage. Then, by expanding this definition, he points out that the causes of secondary hæmorrhage can be referred to one of two conditions—viz., "(*a*) when the lumen of a vessel is opened up by ulceration of its walls (septic arteritis), and (*b*) when the pressure of the blood within it ruptures a healing artery before a strong resisting cicatrix has been formed." It is interesting to observe how either one or other of these conditions, or occasionally a combination of them, contributes to an accident which is far less common than it used to be. Amongst the several topics treated under the head of Diseases of Bloodvessels especial mention may be made of the section dealing with atheroma, phlebitis, and varicose veins. In the surgical treatment of the last-named preference is unhesitatingly given to *excision*, which in most cases is absolutely curative, no fresh development of varicose veins arising, a fact held to prove that varix does not depend alone upon over-distension. In those cases in which new varices do appear after operation, an explanation is to be found in the nature of the particular case, showing that the pathological tendency is still operative. The article on Aneurysm is well-planned and exact. We observe that Mr. Pearce Gould is careful to limit the phrase "cure" in relation to aneurysm to the condition of "organisation" of the clot, which can only be obtained by obliteration of the artery. The diagnosis of aneurysm, and in particular the question of treatment, are discussed with a fulness of detail which renders the article

Digitized by Google

one of great practical value. Descriptions are given of traumatic aneurysm and arterio-venous aneurysm, the article closing with an adequate account of the special features exhibited by aneurysms of particular arteries.

The volume closes with four chapters on Injuries and Diseases of Bones and Joints. That on Injuries of Bones is written by Mr. Stanley Boyd, who deals with his important subject in considerable detail. An accurate and practical acquaintance with the subject of fractures is of vital importance to all practitioners. These accidents are very common, and their treatment has to be undertaken by all except a very few physicians. They are also very varied in their nature, and the successful management of all the complications that may arise in connexion with them often taxes the resources of the most experienced surgeons; and yet they are accidents which the public generally regard as simple, even commonplace, and they are very prone to think that a result short of perfect restoration of the injured part must reflect discredit upon the practitioner in charge. The important thing is to have a clear grasp of the facts of the pathological anatomy of fractures, and to understand the mode of repair of these injuries. Mr. Boyd discusses the varieties of fracture, their symptoms, complications, and mode of union most fully, and our chief criticism of his article is that if anything he has been too diffuse and too elaborate and full for what is after all a student's text-book. The illustrations to this chapter are both numerous and excellent—a real assistance to the reader.

Mr. Clutton follows with a chapter on Diseases of Bones. This is a fascinating subject, and dear to every surgical pathologist. Mr. Clutton deals with it in a style that is in strong contrast to Mr. Stanley Boyd's—very concise and in places even too brief. The views enunciated are, of course, those current to-day, but Mr. Clutton is not pedantic and still writes of pus spreading along a bone under the periosteum, although the reader must clearly understand that the results described are due to the presence of infective organisms, and that to their spread is due the spread of the disease. Mr. Marmaduke Sheild writes on Injuries of Joints, especially Dislocations, and he has succeeded in describing tersely and clearly injuries which have too often been imperfectly pictured. The chapter is a thoroughly practical one and the illustrations are really useful, especially those showing in exact detail the special manipulations required for the reduction of dislocations. A good account of congenital dislocation of the hip-joint is given, and the various operations which have recently been devised for this deformity are described.

The chapter on Diseases of Joints is by Mr. A. E. Barker, who has devoted great attention to this important subject, and who, therefore, writes upon it with authority. Much excellent work in both the pathology and treatment of diseases of joints has been accomplished during the last few years, and the main results obtained will be found duly recorded by Mr. Barker. The injection of iodoform emulsion into tuberculous synovial membrane is recommended, but no mention is made of the similar use of other germicides such as chloride of zinc. Syphilitic diseases of joints are described; but we find no account of the deep worm-eaten erosions of articular surfaces occasionally met with in tertiary syphilis, and of which such admirable specimens were exhibited last week in the Pathological Museum of the British Medical Association. Following the description of diseases of joints in general is an account of the diseases of the individual joints. This part of the article is admirably done, and is a capital *résumé* of our present knowledge and current practice.

To this first volume of his System of Surgery the editor contributes only brief articles on such subjects as the influence of constitutional conditions upon injuries, tuberculosis, hæmophilia, and hysteria in its surgical relations; his more important contributions will be found in the second volume. The remaining article is on Anæsthetics, and is written by Dr. F. W. Hewitt, whose experience in this subject and ability in writing upon it are well known. We have already spoken of the work as being well printed and abundantly illustrated. A large number of the illustrations are original, and most of them have been executed by Mr. Berjeau. On the whole these illustrations are excellent, but some of them are coarse and ugly, and distinctly inferior. The illustrations in the chapters on Fractures and Dislocations will be particularly appreciated by students.

In conclusion, we must heartily congratulate all those who have been associated in the publication of this volume on the great measure of success they have attained. It is a thoroughly reliable text-book, accurate, fully abreast of current knowledge, and quite equal to any of its rivals. We anticipate that if the second volume equals this one in merit the work will meet with great and deserved success.

Hygiene and Public Health. By LOUIS C. PARKES, M.D. Fourth Edition. "Practical Series." London: H. K. Lewis. 1895.

SINCE 1889 three editions of this work have been exhausted, and a fourth is now being issued to the public. The author draws attention to the circumstance that the new edition has been revised, and to a slight extent enlarged where necessary in order to keep abreast of advancing knowledge. The book now contains 520 pages, is well illustrated, and sufficiently indexed. As in former editions, the best chapter is the one devoted to the Disposal of Refuse, than which we believe no clearer or better description is given in any text-book. The chapter on Food, Beverages, and Condiments is also an excellent one. The pages on The Contagia, although fairly practical, are not brought sufficiently up to date. Neither in the chapter on the Contagia nor in that on Communicable Diseases is any reference made to the recent researches relative to the finding of the typhoid bacillus in the urine and in the eruption, nor to its probably infrequent and accidental appearance in the alimentary canal. The author evidently still regards typhoid fever as an intoxication process. When he refers to the bacillus of typhoid fever "as almost constantly present in the alimentary canal," he is of course confusing what is now believed to be the true typhoid bacillus with the bacillus coli communis, the latter being a normal inhabitant of the intestine, although he afterwards gives some of the chemical tests which differentiate the two bacilli. Recent researches show that when the bacillus coli communis and the typhoid bacillus are grown together in the same medium the former kills the latter, and this fact, no doubt applies equally to the life-period of these bacilli in the intestine. We are glad to see that the new edition is not over-burdened with figures, and for this reason it will no doubt be very acceptable to the busy practitioner.

MAGAZINES FOR AUGUST.

The Practitioner.—The journal edited by Mr. Malcolm Morris is one of the most interesting of the monthly medical magazines. The original communications include a very clearly written lecture on Hare-lip by Mr. Christopher Heath, illustrated with photographs of three degrees of the malformation. The lecture is full of thoroughly useful and practical hints. Dr. Goodhart refers in an apologetic manner to a complication of influenza—viz., Thrombosis; Mr. Rose writes on Enterectomy by Maunsell's method, and the editor on a Method of Staining the Fungi of Ringworm. Dr. Caley in Comparative

Digitized by Google

Studies considers Perityphlitis, and there is a sound article upon Disinfection. The Medico-Literary Causerie deals with Fees, Ancient and Modern; the balance is much in favour of the ancient scale, for to quote an example, which the writer omits, Demokedes, a Greek physician in slavery at Susa, cured Darius, who had sustained a bad sprain. For this the King gave him as many chains in gold as had previously loaded him in iron. He also introduced him into his harem, when each Sultana gave him a dish full of golden staters, and the stater was worth about £1 1s. "Fancy that now," to quote Hedda Gabler's weak husband. Reviews of the medical science, abstracts from foreign journals, and therapeutic notes make up a good number.

Chapman's Magazine.—The *pièce de résistance* this month is Miss Mary Wilkins's prize detective story. It is a new line for the talented authoress of "A New England Nun," and in some ways she has succeeded very well. Her character-drawing is excellent, and the tale has all the elements of a popular detective story—plenty of mystery and the skilled amateur detective; but the medico-legal element is marvellously incorrect. Mr. Fairbanks is murdered by a lady dressed in overalls. She stabs him over the heart with a pair of shears "a little after midnight." She, or rather the overalls, get covered with blood, and she slips into a cupboard in the daughter's room, when, feeling herself wet with blood, she catches hold of a dress hanging in the cupboard and wipes the stains with it. She also very imprudently leaves bloody hand-marks upon doors and shelves, and bloody footsteps on the floor, so the hæmorrhage was evidently profuse. The daughter gets up at five o'clock and finds her blood-stained dress in the cupboard *with the stains still wet*. Now, punctured wounds of the heart do not bleed freely externally, especially when the recipient of the wound is lying down, as in this case. Also the night is mentioned as being very hot, so the blood stains on the dress in the cupboard would have had ample time to dry between 12.30 and 5 A.M. These errors mar a really good story. Mr. Eden Philpotts's Demon Conger is good, and the asphyxia convulsions are well done.

The Humanitarian.—The first article in this periodical is Mr. Grant Allen's amusing denial of the charge of "culture." To call a man cultured is almost as bad as calling him "aimiable." Dr. Forbes Winslow writes in the manner of Lombroso about the madness of genius, and Mr. J. Rice Byrne returns to his thesis that corporal punishment in schools is an accursed thing. He is evidently referring to schools under the Education Department, but even in them we think that an occasional flogging is most wholesome. Eton boys, Uppingham boys, Harrow boys, Winchester boys, and Westminster boys are all "swished," why should not other schoolboys be so too when it is called for, as it often is?

New Inventions.

A NEW UREAMETER.

A NEW ureameter which I have designed possesses the following points of advantage. It is extremely portable and simple, but it nevertheless estimates the amount of urea in urine with accuracy; moreover, only a small amount of sodium hypobromite solution is required for each estimation. The accompanying sketches will show the shape of the instrument. It is held in the position shown in Fig. 1, and about half filled with hypobromite solution. A cubic centimetre of urine is put into the little test-tube, which is then gently placed in the larger open end of the ureameter, and this is corked up. By turning over the whole thing in the direction of the hands of a clock to the position shown in Fig. 2 the urine is mixed with the hypobromite solution, and the whole of the nitrogen given off is registered by the level of the

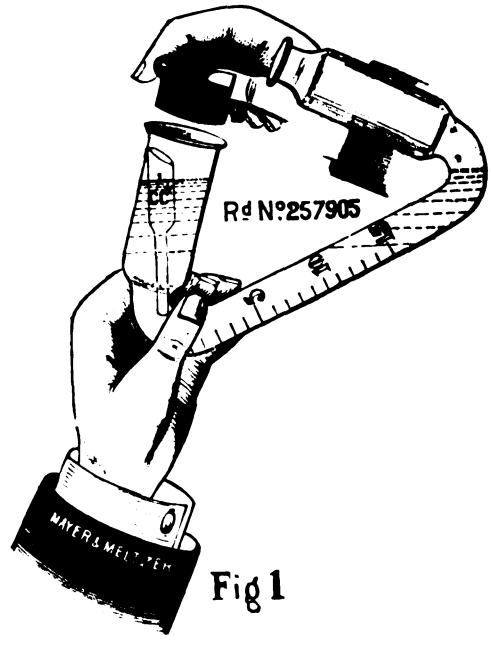

Fig 1

liquid in the graduated tube. After reading the indication, by turning round the instrument still further in the same direction as before, all the hypobromite solution which has not been in contact with the urine may be emptied back into

Fig 2

the stock bottle. It is evident that with this ureameter none of the nitrogen escapes into the open air, and the amount of hypobromite solution used is very small. Messrs. Mayer and Meltzer are the makers.

THE LANCET.

LONDON: SATURDAY, AUGUST 10, 1895.

THE British Medical Association has reached its grand climacteric. It has held its sixty-third annual meeting, and the most prejudiced critic must allow that there have been few associations which could show more splendid achievements. The meeting itself was an achievement. Its numbers, its hospitalities, the quality of the addresses delivered by the President and the leaders of the Sections, the work of the Sections, the presence of distinguished foreigners, the wide recognition of it as an event by the general press, are features of the meeting which may fill all its promoters with just pride. Add to this the numbers of the Association itself, and we may dare to believe that the members of the Executive, those who feel the responsibilities of leadership, were never more satisfied with the Association than they are to-day. We ventured lately to say that the Association had been more successful in the discussion of questions affecting the science and art of medicine than of those which affect the interests of general practitioners. We are not vain enough to think that this friendly criticism is the sole explanation of the development of interest in these questions which characterised the proceedings of the recent meeting. But the interest shown was truly enormous. On the first day of the meeting and on the last the discussion of such topics formed a feature which must strike the most casual observer. Indeed, this solicitude for the general practitioner came with such a rush as almost to give the impression that if there were not some want of sympathy between the Council and the advanced reformers there was at least a difference of pace which made walking together rather difficult. On the midwives question the Council had come to a resolution which all responsible persons who have reflected on the matter seriously have reached long since. Dr. WARD COUSINS said that the Council had given days and nights to the consideration of this subject—not too much for the mature of the interests involved—and the first conclusion that they had come to was that "the present state of things was intolerable, and that a change was absolutely necessary." He then indicated the lines on which the Council had requested the Parliamentary Bills Committee to frame a measure for the registration of medical, surgical, and midwifery nurses. The Council recommended the substitution of the word midwifery nurse for that of midwife, and while recognising that every case of midwifery could not be attended by qualified practitioners, insisted that every registered nurse should be in touch with a qualified practitioner. This was essentially the proposal of Mr. LAWSON TAIT in the following resolution, which was carried by a large majority.

"That we, the members of the British Medical Association, while anxious to improve the training and supervision, and, if need be, support a practical scheme for the registration of medical, surgical, and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical or surgical or midwifery practitioners other than those recognised under the Medical Act, 1886, as now existing."

It may be a matter of question whether Parliament will accept the absolute obliteration of the word midwife; but it is satisfactory that the Association has come to accept the views of the General Medical Council, and of its own council, in respect of the training, supervision, and registration of women—by whatever name they are to be known—who will stop a gap in ordinary labours among the very poor, which registered medical men cannot stop, and, as Dr. SCHARLIEB gave distinct notice, registered medical women are not prepared to stop. This resolution is an end to all controversy on the main question. But we cannot leave the subject without expressing our wonder that in arguing it Mr. LAWSON TAIT should have thought it necessary to castigate the Council of the Association for requesting the Parliamentary Committee to formulate the very views, which he expounded and which are now universally accepted. Sir WALTER FOSTER said that when the Bill came out of the committee all definition and limitation of function (of midwifery nurses) was gone. This must refer to the Committee of the House of Lords. But it is not, we think, an accurate statement. As we read the Bill the limitation of function to cases of natural labour remains in the fourth clause and is assumed all through. On another subject Sir WALTER FOSTER gave the impression that he considered the Council one of the most prejudiced bodies that he has encountered. We are no blind admirers of the General Medical Council, neither shall a disposition to do it general justice prevent us from expressing our satisfaction with Dr. LOVELL DRAGE'S resolution dealing with the monstrously inadequate recommendations of the General Medical Council as to the training of medical students in midwifery, requiring that they shall have been present at only nine confinements and have personally conducted "only three." Dr. DRAGE'S resolution, which was carried, also instructed the Council to seek the repeal of the section of the Metropolitan Poor-law Act which prevents workhouse infirmaries being used for clinical instruction of medical students.

Another lively subject came before the general meeting on the first day—the assumption by the British Medical Association of the functions now discharged, and very ably discharged by the Medical Defence and Protection Societies. The chief interest of the discussion was in the illustration afforded by it of a sharp difference of opinion between the Council and the members of the Association on the subject. Dr. WARD COUSINS and his colleagues intimated that the Council were advised that the Association could not accept such functions under the present memorandum, which, like the law of the Medes and Persians, does not seem to admit of alteration. We share the impatience of the members with a mere memorandum. On the other hand, we feel with the Chairman that for sixty-three years the memorandum has served very well, and that there is much to be said for making the work of medical defence the sole work of a special

Digitized by Google

society. It is a mistake to think that one body can do everything. Even the County Council and the British Medical Association may well consent to recognise a limitation of their powers. And the latter body may certainly be content to see other societies doing special work for the good of the profession.

We have not time to deal separately with all the questions opened in the resolutions—eight or ten in number—which were passed on the closing day of the meeting, without adequate discussion and we fear before somewhat small audiences. The Council has its work set out for the ensuing year. It has been requested by several formal resolutions to take steps for the suppression of advertising in all forms; to prevent members of the British Medical Association accepting posts in medical aid and kindred societies; to open a fund for indemnifying those who fight the battles of the profession against combined friendly and benefit societies; to communicate with universities and corporations requesting them to discourage members accepting medical aid and other appointments derogatory to the profession; to approach Government with a view to the constitution of an authority to control irregular practice, "with a preference for the British Medical Association" as that authority; to direct the attention of professors and teachers of medicine to the deplorable want of *esprit de corps* and the need for inculcating this virtue. Besides these, resolutions were passed suggesting an alteration of the constitution of the General Medical Council, condemning the employment of unqualified assistants; averring that those who violated the rules of professional ethics should not be met in professional intercourse, and that members of the British Medical Association should not hold office in any but really public hospitals, or gratuitously attend the inmates of pay wards in such hospitals. It is impossible not to agree with the spirit of these resolutions and the desire to bring the influence of the Association to bear strongly in carrying them into effect. But this is very different from carrying them by the dozen and leaving the *modus operandi* for twelve months in the hands of the Council.

The grand climacteric is an achievement and is full of honours; but it has its own risks and its own lessons of caution. The very size of the Association makes it unwieldy and difficult of control by its council. This is shown when a dozen orders of the first magnitude, involving applications to Parliament, to the General Medical Council, and to all the medical authorities, are hurled upon the council at the last moment of a festive and busy meeting. The council has had a warning that if it does not move a little faster it may have to be superseded by another set of councillors. Some means must be formed to steady the method of procedure by abstract resolution and to coördinate the action of the branches of the council, or else disappointment, not to say disaster and discord, will result.

THE equivocal position of the ductless glands in the animal economy, and the interesting nature of the facts that have recently been ascertained in regard to them, gave a special interest to Professor SCHÄFER'S address in Physiology. The functions of the spleen, thyroid, thymus, and supra-renal capsules have long been shrouded in obscurity, and many points in their life-history still remain to be elucidated. The similarity of the structure of these bodies to that of glands, but unprovided with ducts, their large volume, and the evident activity of the processes that take place in their interior, as indicated by their large vascular and nervous supply, which militates against the supposition that they are useless or that they are mere degenerate remains of once more important organs; and, on the other hand, the possibility of removing the whole or the greater part of their substance without apparent injury to the health of the animal—all these and many other facts combine to render them a physiological puzzle. For many years past, however, the conviction has been growing in the minds of physiologists that their true function consisted in the separation of certain materials from the blood, acting in the same fashion as the salivary glands or pancreas, but that these secretions, instead of being discharged from the surface of the body, as is the sweat, or into the alimentary canal, are reabsorbed into the blood, and fulfil certain definite purposes in the economy. Hence the term applied to them by Professor SCHÄFER of internal secretions. In one sense every part of the body, be it nerve or muscle, bone or fat, modifies the blood in a similar manner by abstracting from the blood the materials of its own nutrition and restoring to that fluid the products of its disintegration. In the cases of the liver and pancreas the internal secretion is more important than the external, since the secretion of the former of these glands at least may be permanently diverted by a fistula without interference with the vital functions, whilst removal of the whole gland is invariably fatal. As our knowledge of the liver and its functions has extended we begin to see the reason of this. The liver visibly secretes bile which may be abstracted before entering the alimentary canal without harm, but it also forms urea and glycogen, and it is the accumulation and decomposition of these products that cause death when the whole gland is removed. Analogous experiments on the pancreas enable similar deductions to be drawn. The pancreatic juice can be diverted by a fistula from the intestine, and the major part of the gland can be cut away without harm, but if the whole be removed death results from diabetes. The internal secretion of the gland is more important than the secretion it discharges by its ducts. After discussing the relations of the thymus and thyroid bodies Professor SCHÄFER dwelt at length on the supra-renal capsules, on which he, with the assistance of Dr. OLIVER and Mr. MOORE, has been working for some years. He sums up his results, which show conclusively that the medullary portion of the adrenals contains a dialysable organic principle, soluble in water and not destroyed by boiling for a short time, which produces a powerful physiological action upon both striated and unstriated muscular tissue, especially affecting the skeletal muscles and the muscles of the blood-vascular system, causing these contractions to be greatly prolonged, and in this respect resembling the action of veratria. It also has some exciting influence on the cardio-inhibitory centres in the medulla oblongata, causing the heart to slow down

Digitized by Google

but after section of the vagi it exercises an opposite effect, increasing the force and frequency of the heart's action, and thus leading to a great rise in the blood-pressure, which is enormously increased by its power of inducing contraction of the muscular tissue of the arterioles. These results, which are quite original, reflect great credit on Professor SCHÄFER and will, we trust, incite him to further inquiry.

THE facilities for higher education have now been open to women for a time sufficiently long to permit us in some measure to estimate the results of the modern movement from which so much has been hoped. In the *Nineteenth Century* for July Mrs. J. E. H. GORDON takes up the subject, and presents much interesting and valuable information. Her method is to take the statistics of Newnham, Girton, and other centres of higher female education, and to trace, so far as practicable, the after-careers of the women who have been trained in these institutions. The object of the writer is "to gain some practical knowledge as to what a university training leads to for women and how far it is worth while for girls to spend some years and some money in acquiring a solid knowledge of the higher branches of learning, such as mathematics, classics, moral science, &c., and whether this course of training does really ultimately make women's lives freer and happier, and if the honours they gain at college enable them to earn their own living by newer and more interesting means than by the old-fashioned methods of teaching, companionship, and needlework." The results of the inquiry are highly interesting, and will probably come as a surprise to most readers. The total number of students who left Newnham College from October, 1871, to June, 1893, was 720. Leaving out those who have died and the foreigners who have returned to their own countries, it would appear that 374 are at present engaged in teaching as a profession, 47 have married, including 9 or 10 of the lecturers and teachers, 230 are living at home, 5 are engaged in medical work, 2 are missionaries, 1 is a market-gardener, 1 is a book-keeper, 2 or 3 are working at charity organisation, and the remainder are for the most part engaged in secretarial work. The number of students who had passed through Girton up to June, 1893, and obtained degree certificates was 335. Of these 123 were engaged in teaching, 45 were married, 2 were missionaries, 6 were in Government employment, 4 were engaged in medical work, and 6 had died. It is to be presumed that the remainder were living at home. The statistics available from the women's colleges at Oxford give similar results. Of the 173 students who left Somerville College between the years 1879 and 1892, 73 are engaged in teaching, 29 are married, and two or three others are engaged in legal or literary work. The larger proportion of the ex-students of Lady Margaret's Hall are engaged in teaching. Holloway College (Egham), Alexandra College (Dublin), and Victoria College (Belfast) show practically the same sort of results. Summing up the statistics, Mrs. GORDON finds that the after-careers of 1486 ex-students of the various institutions have been ascertained. Of these, 680 are engaged in teaching, 208 have married, 11 are medical practitioners or preparing to practise, and medical missionaries, 2 are nurses, 8 or 9 are in Government employment, 1 is a bookbinder, 1 is a market-gardner, and 1 is a lawyer. A curious fact that comes out strongly in the statistics is that marriages are much more frequent among women who take ordinary pass degrees than among those who take honours. Thus, about 1 in 10 of those who take honours at Girton marries, while about 2 in every 5 who take an ordinary degree marry.

"In former days," says Mrs. GORDON, "marriage, teaching, and philanthropy were the principal professions that were open to women. The careful study of the reports published by the women's universities will, I think, incline parents to question if a university training has yet succeeded in opening the doors of any other profession. A few exceptionally gifted women have entered the medical profession, and a few have become workers in other fields, such as bookbinding, market-gardening, &c., but with these very few exceptions nearly all ex-students are engaged in teaching or are preparing to teach, and therefore it would seem that unless a girl has some special capabilities of mind and brain which, combined with a power of organisation, will place her at the head of the teaching profession after her training at the university is completed, she cannot at present hope that the years and the money devoted to her higher education will do very much for her in enabling her to enter upon a money-earning career in the future." As regards the percentage of marriages among university-trained women, different views will be held according to the prepossessions of the individual. The percentage is very low, and the facts are susceptible of various interpretations. It may be that a university education indisposes women to matrimony, or makes them fastidious in their choice, or provides them with a means of livelihood which makes marriage no longer a necessity; or—may it be hinted?—a taste for higher education may not be generally associated with the qualities which win the admiration and affection of men. It is certainly a striking and significant fact that if a woman takes a university career she is much more likely to become a schoolmistress than a wife. Whether this result is one to be deplored or not must be left an open question, but at all events the fact is very important.

The statistics thus elicited do not necessarily involve any disparagement of female higher education. They do, however, lead us to question whether it is either practicable or desirable that such education should become a usual thing among women. Exceptional women there will always be, with uncommon intellect and energy, who prefer an independent career to the quasi-dependence of matrimony. It is extremely important that such women should have the most ample opportunities for developing themselves, and that they should be allowed to exert upon the world whatever influence their intellect and character can justly claim. The world will be richer for such women, and there will be fewer stunted and dissatisfied lives. But the broad fact remains that such cases must remain entirely exceptional, and that the domestic career is the natural destination of the immense majority of women. Nothing can alter the course of nature, and no fine talk about woman's rights or wrongs can obliterate natural distinctions. That most fatuous of cries, "no sex in mind," can only prevail

Digitized by Google

with those who wilfully blind themselves to the teaching of history and the plain facts of daily life. Men and women are complementary the one to the other, and neither can profitably usurp the sphere of the other. The world's harmony and happiness depend upon their being not competitors and rivals, but allies and helpmates. We confess we are surprised to find how few university-trained women have adopted medicine as a career. That there is a place for women in the medical profession we willingly acknowledge, but we doubt if that place can ever be a large one. The heavy toils, constant responsibilities, and incessant anxieties of medical life are very exacting to even picked men. They must necessarily be much more exacting to women.

Annotations.

"Ne quid nimis."

THE DIFFUSION OF SMALL-POX.

THE metropolis has during the month of July experienced a by no means pleasant change in the behaviour of small-pox as compared with its quiescent state during the month of June, when the cases remaining in hospital never exceeded 34 at the close of any one week, whereas the disease made vast strides towards epidemicity in the four weeks of last month. The number of patients still under treatment at the end of the several weeks has progressively increased since the middle of June, when it was only 19, with prospects at that time of gradual extinction. At the end of June it had risen to 34, and in the next following four weeks to 42, 71, 89, and on July 27th to 199; though even here it has not stopped in its upward tendency, as on Aug. 3rd the patients in hospital were as many as 237 in number. The deaths, which in June were only 2, did not rise beyond 5 last month, and of these 3 were registered in the opening week. Of the 5, there were 3 in vaccinated persons aged over sixty years and 2 in persons concerning whose state as to vaccination no information is forthcoming. In the six weeks since the middle of June the admissions to hospitals of the Metropolitan Asylums Board and to the Highgate Small-pox Hospital have been in successive weekly periods 8, 25, 17, 36, 23, and in the fourth week of July 114 cases. Last week the admissions were two-thirds of the occurrences, and numbered 60. The deaths of July have been put down as belonging—3 to Camberwell, and 1 each to St. Pancras and Strand Poor-law districts. Cases have in the last fortnight of July been brought to hospital from twenty-six of the thirty-four Poor-law areas of the metropolis, though most of the cases came from Whitechapel, St. Saviour's, and Mile-end Old Town. As regards the last-named district, Mr. Taylor, the medical officer, states that during recent years the inactivity of the vaccination authority has resulted in many thousands of young people escaping vaccination, only to grow up to swell the ranks of small-pox victims sooner or later. Meanwhile the sanitary bodies of London are generally taking energetic steps for preventing as far as possible the spread of infection, though in some instances such carelessness on the part of the sufferers has been heard of as will go far to frustrate the designs of the health authorities. The occurrence of multiple cases in connexion with shelters has led the Whitechapel Board of Works to pass a unanimous resolution asking the Local Government Board to take steps to bring all shelters under the Common Lodging House Acts and requesting all the other sanitary bodies in London to support their application. Meanwhile the Local Government Board have issued two circular letters in respect of small-pox prevalence, the one to all boards of guardians throughout the country embodying their letter of 1893 and counselling guardians and their officers how they are to proceed in the event of small-pox being introduced to the workhouse and casual wards, and enjoining precautionary measures as to vaccination, revaccination, isolation, and the like; the other letter is to sanitary bodies in London, calling upon them to issue instructions to their health officers to immediately visit each case of small-pox notified, and to take at once all needed steps as to isolation, vaccination, disinfection, and so forth. The letter lays stress on the importance of adequate measures, especially on account of the growth of small-pox in London at a period of the year when the disease is usually at its lowest ebb. Around London small-pox has not displayed any marked disposition to spread, and in the provinces generally it has been but little heard of. Oldham was, perhaps, the most heavily hit place in England, a good many cases having occurred there during last month, and 6 deaths having been registered in the period, 4 of them in one week. The only other large town having fatal small-pox was Liverpool, where a single death was registered in the first week of July. But quite recently the disease has assumed somewhat serious proportions at the village of Thornhill, near Dewsbury, where 3 deaths have already taken place, 1 of them on Aug. 2nd. Some of the patients have been removed to the Batley Infectious Hospital. In Dublin small-pox continues to linger in a menacing manner, seeing that during the four weeks of last month the cases under treatment at the close of each week never varied by more than a unit. The admissions were successively 11, 6, 15, and 9, and against these 41 cases there were 45 discharges and 4 deaths. Of the 4 deaths, 3 were unvaccinated individuals aged under one year, over twenty, and over forty years respectively, and 1 in a person concerning whose vaccination no information is given. There were 35 acute cases in hospital at the end of the first week of July, and 36 three weeks later, the convalescents having fallen in the same period from 12 to 8 in number.

THE SURGERY OF WAR.

OUR readers, and especially our military medical readers, have no doubt perused the excellent address of Sir William MacCormac, President of the Surgical Section of the British Medical Association, at the late meeting. Sir William MacCormac, who has had considerable personal experience of military surgery, and has always evinced a keen interest in this branch of his profession, took for his subject, "Some Points of Interest in Connexion with the Surgery of War." The modern rifle, with its small, hard projectile travelling with enormously increased velocity to a much greater distance and with a precision that were not formerly attainable, has revolutionised modern warfare and introduced changes that have naturally excited great interest. The Lee-Metford rifle in action is at the present moment the subject of investigation in India, it being alleged that the "stopping-power" of its bullet was found, in the experience of the Chitral Relief Force, to have been limited. It is asserted that the long, thin, light projectile of the Lee-Metford rifle leaving the muzzle with very high initial velocity will, under certain circumstances and at short ranges, pass clean through bones and tissues without any splintering or smashing effect, and with so little resulting shock to the wounded as not at once to cripple them, and put an immediate stop to their attacking power. Between the results of experiments on dead animals and inanimate objects and the effects obtained on the living in actual warfare there are differences that can be explained and can be readily

Digitized by Google

imagined. Be all this as it may, and we are not yet sufficiently acquainted with the facts of the Chitral Expedition as to the effect of the projectile on large and long bones of dense structure as compared with thin flat bones, for example, to warrant the formulation of any definite rule, Sir William MacCormac's address is of much interest at the present moment, because it takes up in a scientific spirit and passes in review the results of all the observations that have been made and describes our present knowledge in regard to arms of precision and the surgery of modern warfare. It would be interesting to ascertain the results of the experience of the Japanese in the late Chino-Japanese War on several questions. From a military point of view the stopping-power of the Lee-Metford rifle is an important consideration for the British Army, engaged, as it often is, in warfare with savage or semi-civilised people, whose fighting tactics consist of impetuous charges and sudden onslaughts. As regards the effects of the consistence of the substance through which a projectile passes—whether dense solid fluid or semi-fluid or an admixture of these—much is already known, but much still remains to be accurately determined and on these and various other points Sir William MacCormac has a good deal to say that is both pertinent and practical. The principles of antiseptic surgery have taught us a great deal and revolutionised our ideas of the treatment of gunshot wounds and injuries, as any one may discern who will refer to Guthrie's Commentaries based upon the observations and experience of the Duke of Wellington's time. Not the least part of our knowledge consists, perhaps, in having learnt what not to do as well as what to do in modern warfare. Sir William MacCormac thinks we are justified in believing—although there is high authority for a contrary opinion—that the next great war will be more destructive to human life than any of its predecessors. But very many cases will remain less severe in character, more capable of successful treatment, and less likely to entail future disablement, while improved sanitation and antiseptic methods will enormously increase the proportion of recoveries. It is the unceasing effort of modern surgery to provide antiseptic protection in an effective form in time of war; and in this connexion he recalls the fact that the late medical organisation during our war in Egypt was so complete that not a single case of infective wound disease occurred during the whole campaign.

FAITH-HEALING OR SUICIDE?

AN inquest was recently held upon the body of a girl aged seventeen, who died in Brixton of acute tuberculosis and peritonitis from a perforating gastric ulcer, having been very ill since last Easter. She had no medical advice because, according to the evidence of the woman in whose house she had stayed, "she trusted in the Lord to heal her without medical aid." It is useless to point out to people of this cast of mind the falsity of their theological reasoning, but we do think that the Legislature, which takes care to prevent people jumping off the Monument or going on to ice too thin to bear their weight, might step in and prevent Peculiar People and faith-healers from murdering their children by neglect. We should be the last to deny the power of faith, but, as a recognised authority says, "faith without works is dead," and it is a canon of theology that the Almighty works by means, and those means humanity is bound to use. The *New Science Review* for July contains an article entitled "Has Mental Healing any Scientific Basis?" We do not quite understand this question, but we gather from the article that help need not always come from without, but there is a broad field for "auto-suggestion and systematic concentration with happy results." The way and means to become properly auto-suggestive is as follows. You say mentally to yourself—even mechanically at first—until the habit is formed, "I [the real ego] am well. I am strong. I am pure. I am perfect. I am one with the Divine Spirit of Wholeness." The next step is, "To ensure progress special times and seasons should be set apart for focalized thought and affirmation. ..... At times when the objective world, with all its cares and anxieties, may conveniently be barred out, the full glare of the consciousness is turned upon the Divine ideal within, which thereby gradually becomes graphic and ruling." It is evidently quite easy to become a mental healer, but we seem to remember that this process is not new. There was once a sect in the Eastern Church called the Ὀμφαλοψύχοι, who by steadily gazing at their navels were at length rewarded with a sight of the light (created or uncreated) which shone at the Transfiguration. This method, we suppose, is what Mr. Henry Wood, the writer of the article in question, calls "keeping company with his inner ideal." However, he does not seem to have much faith in the process he recommends, for he concludes: "As related to illnesses, prevention is the end to be sought, so that in time cures may be unnecessary." If anyone by "keeping company with his inner ideal" can cure a gastric ulcer he would be a most valuable addition to our present therapeutic agents.

DEATH REGISTRATION IN THE STRAITS SETTLEMENTS.

DR. DUMBLETON, in a paper recently read before the Straits Medical Association, forcibly called attention to the defects of the present registration system in the Straits Settlements. This system was established by a local Registration Ordinance issued in 1866. Registration under this system is effected through the agency of the police, the householder being responsible for reporting the death at the nearest police station, and for recording the name, age, nationality, and cause of death, with the names of the parents of the deceased person. One of the most serious defects of the system as a basis for trustworthy mortality statistics is the method of recording the cause of death. Diagnosis is largely left in the hands of the police, and to qualify them for this duty a list of about thirty names of diseases and symptoms of diseases, in English, Malay, and Tamil, is hung up in each police station. Among the natives there is probably very little regular medical attendance, but it is stated that when the deceased person has been attended by a medical practitioner a medical certificate is not necessarily asked for, and the cause of death stated in such certificate is by no means necessarily entered in the register, from which monthly returns are copied locally and furnished to the Registrar-General of the Colony. It is not surprising to learn from Dr. Dumbleton's paper that the result of this system, or absence of system, is, as regards causes of death, eminently unsatisfactory. The deaths of most of the adults in the colony are stated to be due to fever and of nearly all the children to convulsions. Under these circumstances it is practically impossible to form any sound opinion as to whether any real progress is being made in the direction of improving the health of the colony. The figures furnished to the Registrar-General from the various local districts are summarised monthly and published in the Government Gazette. It is pointed out that these official returns under this defective system are full of inaccuracies, and that the proportions of births and deaths to the population in a quarter are given instead of the annual rate in the quarter. The deaths recorded in the colony appear to be nearly twice as numerous as the births and were in 1892 equal to 32 per 1000 of the estimated population. It is clear, however, that the registration of births, as is the case in most native populations, is very defective. Of the 5197 deaths recorded in 1892, 1523 were

Digitized by Google

referred to fever, 861 to convulsions, 410 to old age, and 223 to beri-beri. Dr. Dumbleton calls special attention to the high rate of mortality of infants under one year of age, which he states to be equivalent to 338 per 1000 in Singapore against 264 in Bombay and 273 in Calcutta. It should, however, be borne in mind that where the registration of births is so manifestly defective as is the case in Singapore the proportion of deaths under one year of age to births very considerably overstates the true rate of infant mortality. It is not without interest to learn that small-pox in Singapore, though endemic, does not assume a virulent type or materially increase the mortality; that the colony is wonderfully free from cholera and enteric fever; that measles and whooping-cough are rare and mild disorders; and that scarlet fever and diphtheria are in the opinion of most local practitioners at present unknown. Under these favourable circumstances the high death-rate from all causes in Singapore is the more remarkable, more especially as the age and sex constitution of the population is distinctly conducive to a low death-rate. Without trustworthy returns of the causes of death the high death-rate cannot be referred to its true causes, and no such trustworthy returns are possible without the coöperation of the medical practitioners. Bearing in mind how intimately the improvement of the public health in the Straits Settlements is bound up with an improved system of death registration, we trust that Dr. Dumbleton's paper will promote this very desirable reform.

SURGICAL AID TO THE INJURED IN PARIS.

FOR some time past Dr. Marcel Baudouin, the very able and energetic secretary of *Le Progrès Médical*, has been inundating, as he himself puts it, the professional press with articles, all bearing one and the same title—"Instantaneous Surgical Assistance"—and at length there is some reason to believe that the indefatigable efforts of the enthusiastic journalist are about to bear fruit, the director of public help at the Prefecture of Police, M. Auguste Voisin, having recently communicated to the Council of Hygiene and Salubrity of the Seine a project of reorganisation for the relief posts in the city of Paris. It is true the new development thus somewhat ambitiously designated is rather puny, involving merely the provision of two more rooms in the vicinity of the police-stations, but a beginning is always a beginning, no matter how small and feeble it may be, and great ends have ere now been the result of futile commencements. M. Baudouin's comments, as might be expected, are formulated in satiric vein. After quoting the proverb that it takes innumerable taps to fix a nail firmly, he recommends all people with projects similar to that of M. Voisin to beware lest they place them too near the nail, which, by dint of incessant hammering, he hopes eventually to succeed in driving home. When wielding his hammer he has not hitherto been in the habit of crying "*Gare!*"—and such embryonic schemes might very easily get crushed, as though they were so many egg-shells. M. Voisin's project is not a complicated affair, as anyone can see at a glance, and, therefore, its author will in all probability achieve his desires and obtain what he asks for. The injured, it is true, will not be much better cared for than they are at present, but what of that? The authorities will be able to pose as having given the subject their deepest consideration; there will be some modification of existing ashlar work, and a vast amount of paper will be defaced. At any rate, enough will have been done to hoodwink an easy-going public. It is folly to provide a more or less properly fitted dressing-room at a police-station unless there is a competent practitioner in whose charge it can be placed, and whose services would be instantly available at any time during the twenty-four hours. Failing this the place would soon be converted into a centre of infection; ere long the only surgical appliance to be found there would be the sponge common to the entire station, as Professor Terrier felicitously phrased it; and whenever a serious accident occurred recourse would still have to be made to the nearest apothecary as at present. Finally, M. Baudouin complains that such enormous sums should be devoted to the protection of property from fire while so little is granted for the preservation of human life, although the latter, too, possesses a money value and is insurable. A miserable pittance of 45,000 francs has been inscribed in the city Budget for next year in order to provide new ambulances. Ambulances without a properly organised and instantly available *personnel!*—a putting of the cart before the horse which could only emanate from an impractical bureaucrat.

SALVATION ARMY SHELTERS AND SMALL-POX.

AT the meeting of the Vestry of St. George's, Southwark, held on July 30th, Dr. Waldo again made a statement concerning the shelter of the Salvation Army in Blackfriars-road. Nine cases had been notified from there and eight had occurred by direct infection in St. George's Workhouse. Cases had also occurred in Dantzic-street, probably infected from the same source, though this had not actually been proved. Dr. Waldo described how he had visited the shelter and had seen a man covered with the eruption of small-pox. This man was removed to the hospital, but another man who was sitting next to him, and who presumably was infected, escaped into the house, where the "captain" of the shelter refused to let Dr. Waldo search for him, while he himself professed his inability to find him. Therefore the man had to be left—a veritable focus of disease. The cubic feet of space for each individual was but 90 ft., the common lodging-house minimum being fixed by law at 341 ft., while the floor space was but 6 ft., the lodging-house floor space being 31 ft. The law, it appears, at present has no power to close such establishments; they come neither under the Common Lodging-house Act nor the Public Health (London) Act. "The law," said Mr. Bumble upon a memorable occasion, "is a hass," and it certainly seems to be so in this case. Powers should at once be sought by the sanitary authorities to enable them to do away with a standing danger to the health of the community.

THE FIFTH INTERNATIONAL CONGRESS FOR COMBATING THE ABUSE OF ALCOHOL.

ON the 20th, the 21st, and 22nd of this month will be held the Fifth International Congress for Combating the Abuse of Alcoholic Liquors. Its seat will be Bâle, as Brussels was that of the first congress, Zürich of the second, Christiania of the third, and the Hague of the fourth. Its programme includes forty-five papers of diverse lengths, in which the injurious effects of alcoholic indulgence will be treated from every point of view, with practical bearing on their prevention. Physiology, political economy, education and history will, through accredited representatives, have each something to say on the many-sided question which, be it remarked, will be dealt with, not so much by extremists who see nothing but evil in alcohol, as by those who can separate the use of it from the abuse. Nine papers will be devoted to the physiological and psychiatric aspects of alcoholism, and among these the most important are expected to be those of Dr. Legrain, a leading French authority on the subject; of Dr. Hans Buchner, Professor of Hygiene in Munich University, a chair which he holds in succession to Emeritus Professor Max von Pettenkofer; and of Dr. Fürer of Heidelburg, Assistant to Professor Kraepelin in the Chair of Psychiatry. Another interesting page in the discussion of

Digitized by Google

alcoholism is that of its introduction to savage races and the deplorable effects it has produced among them—a page which will be specially entrusted to medico-missionary explorers, English as well as German. The question of State interference, of legalised asylums for dipsomaniacs, and of the various means adopted by diverse nationalities of dealing with the sale of strong drink will also be handled, under the express condition, however, that all political or religious partisanship be wholly excluded. Bâle, it would seem, has an interest of her own in the subject of alcoholism. According to an official "Bericht über den Civilstand, die Todesursachen, und die ansteckenden Krankheiten im Jahre 1893," in that twelvemonth out of seventy-four men between the ages of forty and fifty, eighteen, that is, every fourth man, died of drink; of those between fifty and sixty every fifth man so died; altogether fifty-four victims to alcohol, or every eighth man. Popular attention is always the better for being drawn to such striking figures. In Switzerland especially such congresses—notably that held in Zürich in 1887—have been fraught with good results. A more energetic action in curbing the evil has flowed from them, and the great "Trinker-Asyl" at Ellikon dates its origin from that memorable meeting. Already the Bâle Congress numbers more than 200 "adhesions," and most liberal arrangements have been organised for their lodgment and entertainment. Programmes may be had on application to Mr. G. W. Bronner, 39, Dornacherstrasse, Bâle; while all further information will be freely supplied by the secretary to the Congress, Mr. Hermann Blocher, 26, Weiherweg, or by the president (Professor C. C. Burckhart), 4, Münsterplatz.

IS THERE A PARASITE OF MALARIA?

THE *Times* of the 6th inst. contained a telegram from Hyderabad to the effect that Surgeon-Lieutenant-Colonel Lawrie, assisted by Dr. Martyn Jordan, had demonstrated that the malarial hæmatozoa have no existence in fact, and that the not inconsiderable or inexpert body of microscopists, whose researches have become as familiar as household words, have one and all been deceived by the appearances assumed by leucocytal nuclei under the action of staining reagents. It is really too bad of Surgeon-Lieutenant-Colonel Lawrie to thus shatter at one blow all the fascinating history which the labours of Laveran and Golgi, of Marchiafava, of Manson, and of Thin, not to mention numerous American observers, have opened up to view; and with all respect for our distinguished *confrère* in the Deccan we, in common, we opine, with most pathologists, must decline to admit his interpretation of the characters of the blood in malaria. We would recommend him to carefully peruse the paper which Dr. Thin contributed to our columns a few weeks ago, and to follow the instructions there laid down in the study of the microscopy of the blood before he finally adopts an attitude of such total scepticism. It would, however, be hardly fair to criticise him on the strength of a telegraphic despatch, and no doubt we shall in due course be enabled to study the grounds which have led him to this conclusion. It will require a very convincing series of facts to upset the remarkable observations made in all quarters of the globe which have corroborated and expanded the truth of Laveran's important discovery.

SACRILEGE IN IRELAND.

A CASE was disposed of at the recent Cork Assizes, which is happily sufficiently rare to be of interest. At about six miles from Cork, in the village of Inniscurra, is also the graveyard of the district, on some high ground overhanging the Lee, and in this churchyard is the family vault of Sir George Colthurst, the owner of Blarney Castle. Some two months ago a soldier walking along the road, wandered into the burying-ground, saw the door of the vault open, and noticed that a sacrilege had been committed. He immediately gave information to the police who started to inspect the vault. Coffins had been dragged off the benches and forcibly broken open, while various bones, &c., were scattered about the floor. A leaden coffin had been cut through and the body pulled half out; while the skeleton of a lady was propped high up upon a trestle, and the gloves which had been upon her hands were torn off. This led the police to suspect the stealing of a ring. Eventually the crime was traced to some soldiers of the 10th Hussars. Two of them were returned for trial and sentenced to six months' imprisonment. The judge was of opinion that the crime was unpremeditated, and we earnestly hope it was but a silly freak, for in no country more than in Ireland is reverence for the dead more strictly inculcated and observed, and nothing could be more calculated to keep alive hatred between English and Irish than outrages of this kind, especially when committed by English soldiers, who, to do them justice, are not as a body prone to acts of this class, though sometimes drunken and thoughtless.

THERAPEUTICS OF HIGH FREQUENCY CURRENTS.

THE paper read by Dr. Apostoli on this subject at the meeting of the British Medical Association is an important one, and represents the direct practical application of the physiological facts brought out by D'Arsonval's experiments with animals. The current of high frequency and high potential is caused to traverse a large helix inside which the patient is placed, and the effect is to set up induction currents of a similar kind inside the patient's body. These travel in closed circuits through the tissues and produce nutritive changes, which can be recognised by their effect in increasing the elimination of carbon dioxide and of urea. The actual figures are promised at an early date. The results are good in diseases characterised by failure or impairment of nutrition, and accordingly Dr. Apostoli reports successes in anæmia and debility, gout, rheumatism, neurasthenia, and hysteria. In diabetes also there have been some favourable cases. The principle of the localised application of electricity for the relief of disease, so ably insisted upon by Duchenne, has delayed the recognition of the important general effects to be obtained from electrical treatment. At present there is a distinct movement in favour of general electrification as a therapeutic means, and the results appear to be almost identical in character, whether the method employed be by the alternate current electric bath, advocated by Gautier and Laret, or the high potential induction method of D'Arsonval and Apostoli, or the electrostatic methods favoured by Vigouroux and Morton of New York, who use the Wimshurst or some similar machine as the source of the electricity applied.

COTTON-BORNE SMALL-POX.

IN his annual report for 1894 Dr. Philip Boobbyer, the medical officer of health of Nottingham, furnishes a highly interesting and instructive account of an outbreak of small-pox which occurred in his district, and the spread of which he was able conclusively to trace to infected cotton. His notice was first called to the outbreak on Jan. 15th, when "a suspicious case" was notified as existing in a closed yard situated in the centre of the old town near the lace market, and on proceeding to the spot Dr. Boobbyer, by means of a vigorous house-to-house visitation, brought to light in or near this yard no less than eight cases of small-pox in the course of half an hour. The majority of the cases were recent in origin; but two—a husband and wife—dated back some three and five weeks respectively. In many houses in this infected

Digitized by Google

area was discovered a large quantity of cotton material which had been sent out by two wholesale firms for certain treatment, and wherever this cotton had been in contact with infection Dr. Boobbyer insisted on its disinfection. From subsequent inquiries it was elicited that the husband and wife above referred to had worked at the cotton goods at their own homes throughout their illnesses, and that on Jan. 3rd and 6th they had sent a large amount of cotton to one of the warehouses and at a later date to the others; and Dr. Boobbyer also ascertained that the wife in question was even at the time of his investigation secreting cotton with a view to its transmission to the warehouses, in spite of the fact that she was fully aware of the mischief this material had already wrought. The cotton sent on Jan. 3rd and 6th was all made up, it appears, in one room, and from this room no less than fifteen girls and one youth were absent owing to illness, while three of the remaining eleven showed symptoms of small-pox. On visiting the absentees at their homes they were discovered to be suffering from the same disease. The onset of the attacks occurred between Jan. 14th and 25th, dates which would point to Jan. 3rd and 6th as the time of infection. In the second warehouse into which cotton from the infected family had been received at dates later than Jan. 6th no cases occurred—a fact which, as Dr. Boobbyer observes, tends to the conclusion that at this period the infectivity of the patient had ceased. Thirty other cases occurred in Nottingham as a result of this outbreak, but proper preventive measures were adopted and no fresh cases occurred. The history of this outbreak shows, amongst other things, the danger to which the public may be unwittingly exposed, and therefore the necessity for making use of the protection afforded by vaccination and revaccination; and it is also a good instance of the results of vigorous action on the part of a medical officer of health. Had Dr. Boobbyer not discovered the unnotified cases it is difficult to predict what the extent of the mischief might have been. Instances such as these should, too, bring home to the public the impossibility of properly controlling small-pox without the aid of vaccination and revaccination. If every case of small-pox were recognised and isolated at the very moment it occurred—a purely utopian supposition—much more might be done, save for the nurses and attendants, in the matter of control than is possible now. With, however, the existence of unrecognised cases this disease, a class which experience teaches us includes not only modified but unmodified cases, attempts to properly control the disease without vaccination and revaccination must, as a rule, prove abortive. There are, nevertheless, still some persons claiming authority in this matter who go so far as to assert that if the Medical Department of the Local Government Board were as energetic in the matter of indigenous small-pox control as they are with regard to exotic cholera the former disease would be "stamped out" from this country in six months. All are entitled to express their opinion, and we shall, we trust, be forgiven if we venture to say that statements of the kind referred to show a want of intimacy with the natural history of both diseases as they manifest themselves to those who are brought face to face with their control as medical officers of health. Indigenous diseases such as small-pox or scarlet fever are not "stamped out" in these days—at any rate, by means of notification and isolation. By these methods they may be, and doubtless are, very materially repressed; but, so far as they are concerned, the stamping-out process can only be effected, if at all, by modifying either the human environment or the disease organism.

UNIVERSITY STATISTICS IN SWITZERLAND

THE seven Swiss seats of learning—not including the Polytechnicum at Zürich—during the half year (Winter-semester) 1894–95 had in all 3119 students and 694 zuhörer (auditors), among whom 362 were female students and 238 female auditors. The total number of "Studierenden" amounted, therefore, to 3813, of whom 600 were females. In the study of theology were engaged 449 persons (290 Protestants and 159 Catholics), among them 1 lady (from Geneva); in that of law, 610 (of whom 7 were ladies); in that of medicine, 1081 (of whom 221 were ladies); and in that of philosophy, 1673 (ladies, 171). Of the 3119 students proper, 1847 were Swiss (ladies, 38) and 1272 foreigners (ladies, 324). Germany supplied most of the latter, viz., 394 (ladies 49); Russia, 366 (ladies 212); Bulgaria, 146 (ladies 7), &c. Geneva was the most frequented school, with 815 (ladies 184); Zürich, 808 (ladies 196); Bern, 712 (ladies 125); Bâle, 527 (ladies 11), Lausanne, 516 (ladies 62); Freiburg, 305; Neuenburg, 130 (ladies 22). Theological students were most numerous at Freiburg, 152, and at Bâle, 83. Law chiefly frequented Bern, 150, and Lausanne, 125. Medicine was most largely represented at Zürich, 331, and Geneva, 274. Philosophy numbered 376 at Geneva, Zürich coming next with 308. Compared with the half-year (Winter semester) 1893-94 the students have increased in number by 114.

SIR HENRY PITMAN.

MUCH regret was felt among the numerous friends of Sir Henry Pitman when it became known that he was suffering from the effects of an accident sustained on July 29th. We understand that in crossing a narrow road he passed behind a little cart and the pony suddenly backed, causing Sir Henry Pitman to fall on his hip, which was much bruised. Naturally he was also much shaken, but most fortunately no bones were broken, and his friend and neighbour, Mr. Collyer of Enfield, was able to give a favourable report on the following day. We heartily congratulate Sir Henry Pitman on his escape from more serious injuries, and sympathise with Lady Pitman in her anxiety.

THE TRADE IN DRUGS AND THE MEDICAL PROFESSION.

A ZEAL for modesty of expression does not usually distinguish the processes of commercial ambition. On the contrary, quite another kind of enthusiasm is its inspiring genius, and it is commonly found that simplicity of statement and truth itself are so dressed and altered by self-assertion that their very character is lost within a maze of embellishments. If this property of advertisement were generally recognised and allowed for, if even it were limited in its use to matters of secondary moment, we might contentedly wait for the verdict of experience upon its protestations. But we are still unprotected by any such desirable safeguards. It matters little apparently whether a marketable substance is in itself dangerous or the reverse. There are two allowed judges in such matters, and in many cases two only, the seller and the buyer, the former not disinterested, the latter or both imperfectly instructed. To no branch of business do these remarks apply more forcibly than to the trade in drugs. It is common to find that a variety of dangerous substances are commended in circular notices by non-professional salesmen with a freedom and self-confidence not enjoyed by many clinical authorities. What would be even more amusing if the subject were not one of serious practical importance is the complacency with which the medical profession itself is instructed in these broadsheets as to points of diagnosis and treatment. Not only is the yet remedy commended in its thousand applications, but the general course of medical procedure in relation to various diseases or symptoms is laid down in no uncertain terms. It is obvious that a method so presumptuous in its half-

Digitized by Google

knowledge cannot command the attention of rightly discriminating practitioners. A simpler and a less pretentious attitude would be much more certain of a fair hearing. The duty of Governments in this relation ought not to be overlooked, and in this country it is apt to be regarded somewhat carelessly. The nostrum is viewed in its entirety as a saleable article, and then—*caveat emptor*. This is hardly enough. If the sale and advertisement of such articles are permitted it is, at least, advisable that their composition should be frankly stated. Abroad they order this, among other things, better than in our own free country.

DANGEROUS PERFORMANCES.

IN our issue of June 27th we commented upon the unnecessary danger attending trapeze performances owing to the height at which the apparatus is suspended. On Aug. 1st the father of two children aged twelve and fourteen applied through a solicitor for a licence for the children to perform. It was stated that recently the younger child had fallen. Mr. Sheil refused the application on the ground of the children being too young. This, it appears to us, is not the most cogent reason for objecting to these performances. Training in physical exercises must be begun in youth, but, to repeat our recent argument, these gymnastic exercises should be compulsorily gone through at a reasonable height above the ground. Another lamentable waste of life occurred at a fête held at Peterborough. The "attractions" included a balloon ascent and a double parachute descent by a man and a woman. As the balloon went up the parachute of the woman caught on a telephone wire and fell. When the balloon had risen about sixty feet the woman jumped out and, falling on her head, was killed. The man descended safely. Now this sort of exhibition ought not to be allowed. The making of money out of a morbid propensity on the part of people for enjoying the sight of other people risking their lives should be made a punishable offence. At the inquest the jury returned a verdict of "Accidental death," and we are glad to see added as a rider: "That since no useful purpose is served by these senseless exhibitions, at which the lives of performers are risked, they should be made illegal."

DIPHTHERIA IN LONDON.

DIPHTHERIA continued to show an increase in amount in London during the eight weeks of June and July, the increase having been steadily maintained during that period, though the registered fatal cases in the time have shown some fluctuation, wavering between 33 as a minimum and 53 as a maximum weekly number. But the increase of amount of diphtheria has not had a corresponding increase of per case mortality, this rate having rather shown a slight disposition to decline. On the other hand the number of patients remaining in hospital has progressively increased since the last week of April, when it was 432, to 508 at the close of May, to 633 at the end of June, and to 681 on July 27th. Again, the admissions to hospital can hardly be taken much account of, as they are of necessity not only a varying quantity, but they have been but a small percentage of notified cases, only some 40 per cent., for example, of the patients heard of in London in the four weeks of last month. The unbroken sequence of increase of amount of diphtheria in June gave an average weekly number of 200 cases, but in the succeeding four weeks this average increased by nearly 40 per cent., though the average weekly per case mortality of the earlier month, namely, 19·1, gave place to the lower rate of 17·3. Looking to the records of the eight weeks to the middle of July, and dividing the period into two of four weeks each, we find that the notifications of the earlier period were in London as a whole 718, and that they gave place to 1,047 in the second half, whilst in the whole time there were in Mile End 78 notifications, 82 in Bethnal Green, 83 in St. Pancras, 110 in Greenwich, 134 in Camberwell, 136 in Poplar, and 168 in Lambeth sanitary areas. In the matter of registered deaths the weekly average in June was 38, but in July 47, the weeks of the latter month giving 23, 20, 10 and 14 above the corrected average, or as a whole 47 against the corrected average of 31 deaths. Distributing the deaths in the first four weeks of July among such sanitary areas as had large numbers, the Registrar-General states that in one week there were 4 each in Newington, Hammersmith, and St. Pancras, and 6 in Fulham; in a fortnight, 8 each in Poplar and Bethnal Green, 9 in Mile End, and 12 in Greenwich; in three weeks 12 in Lambeth; and in the four weeks 22 in Camberwell sanitary area. Looking to this state of things in London at the present time, it will be interesting to watch the records of the next few weeks with a view of seeing what effect, if any, the closure of schools will have on the amount and character of diphtheria, whether, in fact, the same effect will be witnessed as Mr. Shirley Murphy has so graphically shown to have been in operation in 1893. In the four weeks treated of last month, out of the total 90 deaths registered, there were 180 in young persons aged between one and twenty years, or 95 per cent. of the whole. During the same period there were 70 deaths from diphtheria registered in Greater London, and of these 32 belonged to the West Ham district, which has now for some time past suffered excessively from the disease.

A JENNER CENTENARY IN RUSSIA.

THE custom of keeping anniversaries of remarkable events is one much honoured in the observance in Russia. Sometimes the period since the event happened is measured by centuries, as when in 1888 the ninth centenary of the Christianising of the Russian race was kept with due solemnity, or, as happened a fortnight ago, when the first centenary of the union of Courland with Russia was made the occasion of several days' festivities. More often (never a day, indeed, passes without) it is the jubilee, or semi-jubilee, or the twentieth, or tenth, or even on one occasion (carrying the practice *ad absurdum*) the fifth anniversary of some official's entry into the public service. A centenary to be observed next year is one of universal interest. On May 2nd (14th), 1896, according to an announcement of the Russian National Health Society, one hundred years will have passed since Jenner made his "first scientific experiment in vaccination." To commemorate the event the society proposes: (1) to offer four prizes for the best works upon vaccination; (2) to collect and publish materials for a history of the practice of vaccination in Russia, and also a short history of the same in Western Europe; (3) to publish a Russian translation of Jenner's works, with his biography and portrait; (4) to organise an exhibition of objects connected with vaccination; and (5) to hold a commemorative meeting on the day of the centenary. Further details will be published later. The task of editing the history of vaccination has been undertaken by Dr. Vladimir Hubert, who is a recognised authority upon the subject.

KILLED BY LIGHTNING STROKE.

DEATH from lightning is, contrary to popular opinion, so rare in this country that special interest attaches to any example of it. The most recently recorded one has, in addition, an element of pathos from the fact that the victim—a medical man—met his death while hurrying to do what he could to relieve a little child suffering from severe burns. Mr. Reese, the medical man in question, lived

Digitized by Google

at Ystradgynlais in the Swansea valley, and his way to the patient led over a high mountain called Drym. When at the summit he apparently entered the focus of a severe storm, and the discharge took place through his body and that of his horse, killing them both instantaneously. It is generally easy to be wise after the event, but a mountain top is always a dangerous place in a storm, for the protrusion of the mass of the mountain above the rest of the earth surface attracts any cloud, more especially one charged with electricity, and anyone crossing this area, like a "point" on a conductor, is extremely likely to determine the direction of the discharge through himself. If Mr. Reese could only have waited on the lower slopes he would have been comparatively safe, but this course his anxiety to reach his patient—who, we may mention, died before he could have arrived—prevented. As it happened, his body would offer a good conductor to the current. He was probably wet, and, being on a horse, had a good earth connexion by means of the horse's four iron shoes so that any discharge between the earth and the cloud would be very likely to traverse his body. Mr. Reese's great popularity in the county where his work lay, combined with the tragically dramatic nature of his death while obeying the call of duty, render his fate a particularly and sadly impressive one, and we desire to express our sincere sympathies with his immediate friends and neighbours in their loss.

CHOLERA.

WE are glad to notice that the views which are held in this country and have so long been advocated in THE LANCET as to the futility of a rigid system of quarantine to keep out cholera are making progress in other countries. Dr. Eugene Farkas, District Superintendent of Public Health, Budapest, in the paper he read at the meeting of the British Medical Association regarding the late visitation of cholera in Hungary, said that the Government made strenuous but unsuccessful efforts in the summer of 1892 to prevent the importation of cholera into that country. The rigid measures adopted caused very grave injury to commerce and trade, but the disease, in spite of these efforts, arrived at Budapest in September of that year, and subsequently made considerable extension in Hungary, mainly in the course of the rivers. The Hungarian Government in November, 1892, abandoned the greater portion of their restrictive measures. A marked change has taken place, too, in public opinion in Hungary regarding the importance of general sanitary measures and in favour of the English methods of dealing with epidemic cholera.

Apropos of the serious outbreak of cholera among the Japanese troops early in June last, followed by its appearance in Corea in July, the occurrence has given rise to the publication of an article in the last number of the Transactions of the Imperial German Board of Health on the spread of cholera as a sequel of war. The paper in question traces the history of the disease, in connexion with the part played by war in its spread, from 1830 to 1866, as shown by the facts collected by Herr A. Hirsch. The disease prevailed extensively in the Japanese Army towards the end of the late Chino-Japanese War, and at one time caused serious alarm to the authorities in Japan.

We have heard relatively little of cholera during the present year in Europe and India. As commonly happens, a period of great epidemic prevalence is followed by one of freedom from cholera, and India during last year, and up to the present during the present year, has been singularly free of the disease. As far as Europe is concerned there have been cases in some of the Government districts of Russia; and it is reported from Galicia that Asiatic cholera has broken out in the towns of Visnovice and Vyzogrod in Russian Podolia, near the Austrian frontier. According to a correspondent of the *Standard*, the disease has much increased of late in the vilayets of Asia Minor. Between May 23rd and July 24th there were eleven hundred and thirty-four attacks and six hundred and seventy-seven deaths officially reported.

News has come to hand of some cases of "cholera" in the vicinity of Paris, but there is at present no authentic information as to its nature.

THE HOLIDAY SEASON AND RAILWAY FACILITIES.

THOSE who have been compelled by circumstances, or who on account of the unsettled state of the weather, have decided to postpone their annual holiday will still find an ample store of trips and tours among the announcements of the various railway companies. Last year we briefly detailed some of these tours, and for the convenience of our readers furnish a similar article this year. Before doing so, however, we should like to draw attention to some of the almost indispensable handbooks issued by the more enterprising of the companies. The Midland Railway is lavish in the literature which it provides for the public. For three pence a Pocket Guide to the Midland Railway of England can be obtained, and besides containing general information of use to the tourist, makes a pleasant companion while actually travelling in the company's carriages. Various objects of interest *en route* are pointed out and the book is well illustrated.

"Where to Stay" is another useful book issued by this company, and contains a list of some of the best hotels in the United Kingdom and abroad, arranged alphabetically. "Summer Tours in Scotland" contains some good views of Scottish scenery, and is an admirable guide for Scottish tourists. The list of furnished lodgings adjacent to stations on and in connexion with the Midland Railway Company will prove of service to travellers on this line. The London and North-Western Railway Company also publish a list of lodgings, and their "Tours in Ireland" give to the tourist just the information he is likely to want. "Summer Tours in Scotland and England" is a similar book issued by the same company.

The London and North-Western Railway.—Every Saturday during August and September a cheap train will leave Euston at 8.15 A.M. for Rhyl, Abergele, Colwyn Bay, Llandudno, Conway, Bangor, Aberystwyth, Barmouth and Llanberis (for Snowdon), and Llangammarch Wells, returning on the following Monday, Monday week, Saturday week or Monday fortnight. The fare to Carnarvon, Harlech, Portmadoc and Llanberis is 22*s.* and to Rhyl 18*s.*, with proportionate charges for the intermediate towns. The tours in the English Lake District are very comprehensive and cheap tourist tickets are issued to many of the principal English towns through which the company's lines run. Till the end of October tourist tickets, first and third class, are issued between Scotland and England and there are charming circular tours in Scotland, including Oban, Fort William, Caledonian Canal, Inverness, Aberdeen, Perth, and the Highlands till Dec. 31st. The company's guide book gives details of seven tours covering the most interesting parts of Scotland.

Special arrangements have been made this year for visitors to Ireland. We give below a selection of six circular tours in the north of Ireland:—

No. 1.—*Vid* Fleetwood to Belfast, thence to Portrush, Londonderry, Enniskillen, Dundalk, Drogheda, and Dublin, returning from Dublin (North Wall), or Kingstown, according to the ticket held, *vid* Holyhead and Chester.

No. 2.—*Vid* Chester and Holyhead to Dublin (North Wall) or Kingstown, according to the ticket held, thence to Drogheda, Dundalk, Enniskillen, Londonderry, and Portrush, returning from Belfast *vid* Fleetwood.

No. 3.—*Vid* Chester and Holyhead to Dublin (North Wall) or Kingstown, according to the ticket held, thence to Drogheda, Dundalk, Enniskillen, Londonderry, Portrush, Belfast, Portadown, Newry, and Greenore, returning *vid* Holyhead and Chester.

No. 4.—*Vid* Chester and Holyhead to Greenore, thence to Newry, Portadown, Belfast, Portrush, Londonderry, Enniskillen, Dundalk, Drogheda, and Dublin, returning from Dublin (North Wall) or Kingstown, according to ticket held, *vid* Holyhead and Chester.

No. 5.—*Vid* Fleetwood to Belfast, thence to Portrush, Londonderry, Enniskillen, Dundalk, and Greenore, returning from Greenore *vid* Holyhead and Chester.

No. 6.—*Vid* Chester and Holyhead to Greenore, thence to Dundalk, Enniskillen, Londonderry, Portrush, and Belfast, returning from Belfast *vid* Fleetwood.

Passengers by either of these tours may break the journey at Belfast, Portrush, Londonderry, Strabane (whence the tourist will be enabled to visit the wild and picturesque scenery of Donegal), Enniskillen (for the Lakes Erne, Ballyshannon, Bundoran), Dundalk, Greenore (for the Mourne Mountains), Drogheda, Dublin, Holyhead, and at any station on the main line between Holyhead and Holywell (inclusive), as also at Flint, Chester, and Crewe; also at Fleetwood, Blackpool, and Preston, if included in the line of route.

Lough Erne.—A pleasure steamer sails each weekday until Sept. 24th, 1895 (weather permitting), from Enniskillen, at 10 A.M. to Belleek, (24 miles), returning from Belleek at 3.15 P.M. for Enniskillen, traversing the whole of the beautiful Lower Lake. Passengers holding North of Ireland circular tour tickets will, on presenting them at the Enniskillen booking-office, be supplied with tickets for the steamer free of charge.

Donegal Highlands.—Excursion tickets are issued at Londonderry (L. and L. S. R.) to Buncrana, Rathmullan, and Letterkenny, for the fine scenery of the Donegal Highlands.

The following table shows the fares from some of the principal towns:—

From—	North of Ireland, Nos. 1, 2, 3, 4, 5, and 6.				
	Vid Dublin (North Wall), Fleetwood, or Greenore.			*Vid* Kingstown.	
	1st Class and Cabin.	2nd Class and Cabin.	3rd Class and Steerage.	1st Class and Saloon.	2nd Class and 2nd Cabin.
Birmingham ...	82 0	65 0	48 0	86 0	68 0
Liverpool	62 0	51 0	40 0	65 0	53 0
London	111 0	84 0	57 0	117 0	88 6
Manchester ...	66 0	53 0	40 0	69 6	55 6

The Midland Railway.—The excursions arranged by this Company from the various stations on their lines embrace Yorkshire, the Lake District, the East Coast, Lancashire Coast, Bath, Bournemouth, and the West of England, Scotland, Ireland, Wales, and the Continent. The circular tour of the Lake District is an admirable one, and tickets are issued from the under-mentioned stations, enabling passengers to make a tour of the most interesting portion of the Lake District, travelling by the following route: *Viâ* Wennington, Carnforth, Grange, Windermere (Lake Side), by steamer up Windermere Lake to Ambleside, thence by Taylor's well-appointed coaches to Keswick through Grasmere, returning by rail throughout *viâ* Penrith, Appleby (passengers finding their own way from one station to the other), and Settle; or the tour may be made in the reverse direction. From London: first class, 86*s.*; third class, 47*s.* Birmingham: first class, 60*s.*; third class, 31*s.* Leeds: first class, 37*s.*; third class, 20*s.* From other stations on the company's lines the fares are proportionately cheap. The journey may be broken at Grange and Cark-in-Cartmel, at Lake Side, Bowness, The Ferry, and Low Wood on Windermere Lake; Ambleside, Keswick, Troutbeck (for Patterdale and Ullswater), Penrith, and Appleby. The tickets are issued subject to the running of the coaches, and will only be available for the coach journey as long as the coaches continue to run. The fares include coachman's fees. For particulars of the coaches running between Ambleside and Keswick, see note above referring to bookings to Keswick direct. On Thursday, Aug. 22nd, cheap excursions will be run to Dublin, Cork, Fermoy, Killarney, Limerick, Castle Connell, Killaloe, Listowel, Mallow, Parsonstown, Thurles, Athenry, Ballina, Galway, Sligo, Westport, Ballinasloe, Dromod, and Roscommon, by the Midland Company's route through the Peak of Derbyshire to the Midland Central Station, Liverpool, and thence by the City of Dublin Steam Packet Company's first-class steamer sailing (weather, &c., permitting) from the Clarence Dock at 11.30 P.M., and on Wednesday, Aug. 14th, *viâ* Morecambe, sailing at 6.0 P.M. The fares from London to Dublin by this excursion are first class and saloon, 42*s.* 6*d.* and third class and deck, 21*s.* 6*d.* On Sept. 6th there is a cheap excursion to Belfast, Londonderry, Portrush, Giant's Causeway, Armagh, Bundoran, Enniskillen, Warrenpoint, Ardglass, Downpatrick, and Newcastle, Co. Down. From London the fares range from 53*s.* 6*d.* first class and cabin, and 28*s.* third class and deck to 68*s.* 1st class and cabin, and 35*s.* third class and deck. Equally cheap excursions will be run to Scotland and to the North of England on Aug 16th. Week-end excursions to Malvern start from St. Pancras Station every Friday and Saturday, returning on the following Sunday, Monday, or Tuesday after date of issue. The first class fare is 25*s.* 9*d.* and the third class 13*s.* Special facilities are made by this company for intending visitors to Southend-on-Sea and half-day trips to St. Albans and Harpenden run every Saturday at two o'clock or a little after at the return fare of 2*s.*

South-Eastern Railway.—The following circular tours have been arranged by this company *viâ* Ostend. Circular tours in Belgium:—

No. 1. London to Brussels and the Banks of the Boucq.—Itinerary: London, Brussels, Namur, Dinant, Yvoir, Namur, Brussels, and return to London, First Class, £3 16*s.* 8*d.*; Second Class, £2 16*s.* 4*d.*

No. 2. London to Brussels and the Banks of the Meuse.—Itinerary: London, Brussels, Namur, Dinant, Eprave (for Grottos of Rochefort and Han). Brussels, and return to London, First Class, £3 18*s.* 9*d.*; Second Class, £2 17*s.* 9*d.*

No. 3. London to Brussels and the Banks of the Embleve.—Itinerary: London, Brussels, Liege, Chandfontaine, Spa, Trois-Ponts, Stoumont, Rivage, Liege, Huy, Namur, Dinant, Namur, Brussels, and return to London, First Class, £4 7*s.* 11*d.*; Second Class, £3 4*s.* 4*d.* The tickets for these tours from Brussels are available to return within thirty days from the date of stamping at the Brussels Station, and are issued in conjunction with return tickets from London to Brussels, which are available to return within one month from the date of issue. The fare *viâ* Calais is £1 more in each instance.

London to Paris, the Centre of France and the Pyrenees (available for forty-five days).—1st Itinerary: Folkestone or Dover, Boulogne or Calais, Paris, Bordeaux, Archacon, Mont de Marsan, Tarbes, Bagneres-de-Bigorre, Montrejean, Bagneres-de-Luchon, Pierrefitte, Pau, Bayonne, Bordeaux, and Paris to London, or the route may be reversed beyond Paris.—2nd Itinerary: Folkestone or Dover, Boulogne or Calais, Paris, Toulouse, Bagneres-de-Luchon, Bagneres-de-Bigorre, Pierrefitte, Tarbes, Mont de-Marsan, Archacon, Bordeaux and Paris to London, or the route may be reversed beyond Paris.—3rd Itinerary: Folkestone or Dover, Boulogne or Calais, Paris, Bordeaux, Archacon, Dax, Bayonne, Pau, Pierrefitte, Bagneres-de-Bigorre, Bagneres-de-Luchon, Toulouse, and Paris to London, or the route may be reversed beyond Paris. First Class, £11 7*s.* 3*d.*; Second Class, £8 9*s.* 8*d.* These tickets can be extended for three periods of fifteen days each on payment of 10 per cent. on the original fare for each extension.

London to Paris and the Banks of the Loire.—1st Itinerary: Folkestone or Dover, Boulogne or Calais, Paris, Angers (*viâ* Blois or Vendome or *viâ* Chartres, without stoppages on the Western Line), Guerande, Le Croisic, Saint Nazaire, Nantes, Angers, Saumur, Langeais, Loches, Chenonceaux, Tours, Amboise, Blois, Orleans, and Paris to London, or the route may be reversed beyond Paris. Available for forty-five days between London and Paris, and thirty days for the tour beyond Paris: First class, £8 3*s.* 9*d.*; Second Class, £6 0*s.* 4*d.*—2nd Itinerary: Folkestone or Dover, Boulogne or Calais, Paris, Langeais, Tours, Loches, Chenonceaux, Amboise, Blois, Orleans, and Paris to London, or the route may be reversed beyond Paris. Available for forty-five days between London and Paris, and fifteen days for the tour beyond Paris: First Class, £6 18*s.*; Second Class, £5 2*s.* 10*d.*

(To be continued.)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6663 births and 4207 deaths were registered during the week ending Aug. 3rd. The annual rate of mortality in these towns, which had increased in the seven preceding weeks from 15·4 to 22·5 per 1000, declined again last week to 20·7. In London the rate was equal to 21·4 per 1000, while it averaged 20·2 in the thirty-two provincial towns. The lowest rates in these towns were 10·0 in Halifax, 10·5 in Huddersfield, 11·8 in Brighton, 13·1 in Birkenhead, and 13·5 in Derby; the highest rates were 23·8 in Bolton and in Manchester, 24·0 in West Ham, 25·3 in Salford, 26·8 in Norwich, 28·0 in Wolverhampton, and 30·0 in Liverpool. The 4207 deaths in these towns included 1181 which were referred to the principal zymotic diseases, against 1137 and 1255 in the two preceding weeks; of these, 854 resulted from diarrhœa, 115 from measles, 76 from diphtheria, 53 from whooping-cough, 47 from scarlet fever, 33 from

Digitized by Google

"fever" (principally enteric), and 3 from small-pox. Among the large towns the lowest zymotic death-rates occurred in Halifax, Gateshead, Swansea, and Huddersfield, and the highest in Salford, Norwich, Liverpool, West Ham, and Leicester. The greatest mortality from measles occurred in Manchester, Blackburn, and West Ham; from scarlet fever in Huddersfield; from whooping-cough in Blackburn; and from diarrhœa in West Ham, Birmingham, Nottingham, Liverpool, Sheffield, Salford, Norwich, and Leicester. The mortality from fever showed no marked excess in any of the thirty-three large towns. The 76 deaths from diphtheria included 57 in London, 3 in Cardiff, 3 in West Ham, and 2 each in Bristol and Birmingham. Two fatal cases of small-pox were registered in Oldham, and 1 in London, but not one in any other of the thirty-three towns. There were 237 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 3rd inst., against 71, 89, and 199 at the end of the three preceding weeks; 60 new cases were admitted during the week, against 36, 23, and 115 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2423, against 2241, 2267, and 2347 on the three preceding Saturdays; 247 new cases were admitted during the week, against 352, 220, and 249 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 193 and 185 in the two preceding weeks, further declined to 171 last week, and were 13 below the corrected average. The causes of 54, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Portsmouth, Cardiff, Norwich, Nottingham, and Salford, and in thirteen other smaller towns; the largest proportions of uncertified deaths were recorded in Birmingham, Sheffield, Bradford, Preston, and Leicester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·2 and 18·3 per 1000 in the two preceding weeks, declined to 18·0 during the week ending Aug. 3rd, and was 2·7 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·7 in Edinburgh and 17·1 in Glasgow, to 21·4 in Dundee and 28·3 in Paisley. The 520 deaths in these towns included 55 which were referred to diarrhœa, 12 to whooping-cough, 7 to measles, 5 to "fever," 3 to scarlet fever, 2 to diphtheria, and not one to small-pox. In all, 84 deaths resulted from these principal zymotic diseases, against 91 and 92 in the two preceding weeks. These 84 deaths were equal to an annual rate of 2·9 per 1000, which was 2·9 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 48, 57, 72, 61 and 64 in the preceding five weeks, declined to 55 last week, and included 28 in Glasgow, 7 in Dundee, and 6 each in Paisley and in Greenock. The deaths from whooping-cough, which had declined from 18 to 7 in the three preceding weeks, rose again to 12 last week, and of these 5 occurred in Glasgow, 4 in Dundee, and 3 in Aberdeen. The fatal cases of measles, which had been 14, 8, and 11 in the three previous weeks, fell again to 7 last week. The 5 deaths from "fever" showed an increase of 2 over those in the preceding two weeks, and included 2 in Aberdeen, and 2 in Leith. The fatal cases of scarlet-fever, which had been 6, 6 and 3 in the three preceding weeks, were again 3 last week; and the deaths from diphtheria, which had been 1, 1, and 4 in the three preceding weeks, fell again to 2 last week. The deaths referred to diseases of the respiratory organs in these towns, which had been 57 and 59 in the two preceding weeks, further rose to 77 last week, and were 23 more than the number in the corresponding week of last year. The causes of all the deaths registered last week were duly certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·1 and 23·9 per 1000 in the two preceding weeks, rose again to 25·7 during the week ending Aug. 3rd. During the past five weeks of the current quarter the death-rate in the city has averaged 23·9 per 1000, the rate during the same period being 21·4 in London and 15·9 in Edinburgh. The 172 deaths registered in Dublin during the week under notice showed an increase of 12 over the number in the preceding week, and included 25 which were referred to the principal zymotic diseases, against 21 and 28 in the two preceding weeks; of these, 17 resulted from diarrhœa, 3 from small-pox, 2 from scarlet fever, 2 from whooping-cough, 1 from "fever," and not one from measles or diphtheria. These 25 deaths were equal to an annual rate of 3·7 per 1000, the zymotic death-rate during the same period being 6·6 in London and 1·1 in Edinburgh. The fatal cases of diarrhœa, which had increased from 10 to 24 in the three preceding weeks, fell again to 17 last week. The 2 deaths from whooping-cough showed a decrease of 1 from the number in the two previous weeks. Two deaths from scarlet fever were registered last week, but not any during the three preceding weeks. The 172 deaths in Dublin last week included 40 of infants under one year of age, and 31 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers in the two previous weeks. Eight inquest cases and 8 deaths from violence were registered; and 59, or more than a third, of the deaths occurred in public institutions. The causes of 11, or more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-COLONEL TAYLOR having returned from special service with the Japanese Army has been appointed Principal Medical Officer of the South-Eastern District, and has assumed Charge at Dover. Brigade-Surgeon-Lieutenant-Colonel Hughes has taken over the Medical Charge of the Western District. Surgeon-Captain Boles has been appointed to Shoeburyness. Surgeon-Captain Holt has arrived in England on completion of a tour of service at the Cape. Surgeon-Major Barratt has arrived from India on sick leave and Surgeon-Captain Jennings from Egypt. Surgeon-Captains Rowan and Shine have re-embarked for Malta.

ARMY MEDICAL STAFF.

Surgeon-Captain John Francis S. Fowler, M.B., resigns his commission. The following Surgeon-Lieutenants to be Surgeon-Captains:—Harry A. Hinge; James G. McNaught, M.D.; Hubert A. Bray; Thomas McDermott, M.B.; Edward W. Slayter, M.B.; Hugh S. Thurston; Lancelot P. More, M.B.; Charles O'C. Hodgens; Arthur F. Tyrrell; Theophilus P. Jones, M.B.; George S. Walker, M.B.; William J. Smyth, M.D.; William D. Erskine, M.B.; Albert G. Thompson, M.B.; Alexander G. Chambers; George A. Moore, M.B.; Richard C. Lewis; Reginald F. E. Austin; Henry W. H. O'Reilly, M.B.; Nicholas Marder; Edgar H. Condon, M.B.; Gerald S. Mansfield, M.B.; Frederick G. Faichnie; and Harold W. K. Read. Surgeon-Major-General John B. Cole Reade, C.B., retired pay, late Army Medical Staff, to be Honorary Surgeon to the Queen, vice Deputy-Surgeon-General J. A. Bostock, C.B., half-pay, deceased.

NAVAL MEDICAL SERVICES.

The following appointments are announced:—Fleet-Surgeon J. K. Conway, M.D. to the Royal Marine Depôt, Walmer. Staff-Surgeons: J. E. Penn to the *Philomel;* H. E. Marsh to the *Cormorant* for Gibraltar Hospital; and J. C. Dow to the *Northampton*. Surgeons: J. F. Barter to the *Pembroke*, additional; and H. S. Archdall to the *Excellent*, additional; and F. Fedarb to the *Victory*, additional.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant John C. Wright having vacated his Volunteer Medical appointment, ceases to be an Officer of the Army Medical Reserve of Officers.

VOLUNTEER CORPS.

Artillery: 2nd Sussex: Surgeon-Captain H. Colgate, M.D., to be Surgeon-Major. The Tynemouth (Western Division, Royal Artillery): Lieutenant E. W. Bourne to be Captain. 16th Middlesex (London Irish): Edmond William St. Vincent Ryan, Gent., to be Surgeon-Lieutenant. *Rifle:* 1st Volunteer Battalion the Northumberland Fusiliers: Surgeon-Lieutenant D. Stewart to be Surgeon-Captain. 2nd Volunteer Battalion the Gordon Highlanders: Surgeon-Major C. C. Greig to be Surgeon-Lieutenant-Colonel. 1st Volunteer Battalion the King's (Shropshire Light

Digitized by Google

Infantry): George Arthur Tailer, Gent., to be Surgeon-Lieutenant.

PRACTICE IN THE OPEN FIELD IN SWITZERLAND.

On Sunday, the 28th ult., the Militärsanitätsverein of Zürich and the Samaritervereine of Aussersihl, Birmensdorf, and Wiedikon went through a series of evolutions on a considerable scale by way of practice in the event of war. Their field of operations was the rather difficult ground lying between the villages of Uitikon, Birmensdorf, and Urdorf, and the scorching sun that prevailed throughout the day put their service to a severe trial. By 7 A.M. 100 male and female members of all sections were on the ground, those of the Damensektionen (lady sections) being in great force. Under the command of First Lieutenant Dr. Kruker-Wegmann the *personnel* was distributed into three main bodies, each of which had its special head, The various subordinate posts were then filled up and the day's practice commenced. The principal Verbandsplatz (rendezvous for surgical treatment) was the Löwen estate, near Uitikon; another rendezvous of the kind was in a field a quarter of an hour's march distant, and the third Verbandsplatz was considered as the line of battle, in the vicinity of Urdorf, not far from the banks of the Reppisch. Those two latter Plätze were entrusted to the sanitary instructors, Dr. Erne and Dr. Jäger, and three surgeons, Dr. Eberle, Dr. Bryner, and Dr. Schmid, were on duty with the respective main bodies. Each of these latter took up its assigned position and went through the necessary preliminaries for the picking up, the transport, and the tendence of the wounded. Their stations were distinguished by flags, straw mats were in readiness, the "Lagerplätze" for the wounded were marked off in accordance with the severity of the wounds, all implements were *en évidence*, "Trägerketten" (chains of carriers) were formed, and then the first relays of wounded were brought in from the front. These were partly conveyed on litters, partly assisted on foot by attendants belonging to the Samaritervereine, according to the nature of their wounds, and were at once subjected to first treatment. This was performed on the Trappenverbandplatz, and shortly thereafter, by means of wagons, they were transported to the Hauptverbandplatz. So far everything went forward with precision and effect. At the Hauptverbandplatz the wagons as they came up were relieved of their wounded inmates and transferred to the Lagerstellen, where the required surgical and medical aid was performed with admirable punctuality and care.

ARMY MEDICAL SCHOOL AT NETLEY.

The seventieth or summer session of the Army Medical School, Netley, was brought to a termination on July 31st, when Brigade-Surgeon-Lieutenant-Colonel Notter announced the results of the examination, and Surgeon-General Sir Joseph Fayrer, K.C.S.I., presented the prizes to the successful surgeons on probation in the presence or a distinguished company. The following are the lists of those who were successful and who are recommended for commissions:—

BRITISH MEDICAL SERVICE.

	Combined Marks.		Combined Marks.
*L. F. Smith	5251	J. V. Forrest	3943
R. J. Blackham	4807	H. W. Grattan	3879
S. H. Fairrie	4361	F. H. Gunter	3541
G. T. K. Maurice	4245	J. H. Campbell	3461
R. Fawssett	4117	J. Grech	3443

* Gained the 2nd Montefiore Prize and the de Chaumont prize in Hygiene.

INDIAN MEDICAL SERVICE.

	Combined Marks.		Combined Marks.
*J. Stephenson	5921	R. F. Standage	4274
F. N. Windsor	5127	A. A. Gibbs	4066
†W. B. Turnbull	5068	F. L. Blenkinsop	3937
‡R. E. Waters	4847	A. Moore	3924
A. Leventon	4600	H. A. F. Knapton	3848
P. F. Chapman	4481	E. M. Illington	3829
A. Hooton	4467	T. E. Watson	3631
A. F. W. King	4421	C. G. Webster	3538

* Gained the Herbert Prize of £20, the Parkes' Memorial Medal, the Martin Memorial Medal, and the Prize in Pathology.
† Gained the 1st Montefiore Prize of 20 guineas and Bronze Medal.
‡ Gained the Maclean Prize for Clinical and Ward Work.

After distributing the prizes Sir Joseph Fayrer delivered an admirable address to the young officers, the text of which will be found on page 319 of our present issue. The proceedings were brought to a close by Surgeon-Major-General Giraud, Principal Medical Officer, Netley, who briefly thanked Sir Joseph Fayrer for his address. The company was subsequently entertained at luncheon in the Army Medical Staff mess.

THE FRENCH EXPEDITION IN MADAGASCAR.

As regards the health of the French force in Madagascar it is, as we have said, only to be expected that there will be a good deal of inefficiency from sickness. The troops are mostly young men and the climate hot and malarious, added to which the difficulties of transport and commissariat are considerable. Official news from the seat of operations is scarce. The French War Office and Admiralty have not escaped much adverse criticism, and there seems to have been a good deal of delay in getting the troops out of the unhealthy lowlands; but General Duchesne is, by all accounts, a man of military ability and energy. The success of the expedition will mainly turn on the troops being able to reach Antananarivo before the rains, which set in in October, for the amount of sickness will be seriously increased among troops on the march during the rainy season. The French have not had much experience of late of field service of this nature, and there is necessarily much to be learned which can only be ascertained from the results of local knowledge and experience. The French medical service is believed to be well organised and equipped, but a great strain on all departments is only to be expected, and every effort will now have to be made to feed the troops and avoid their exposure as much as possible during the rains. As far as is known at present the sick-rate amounts to about one-tenth of the force; the death-rate is low.

DEATH IN THE SERVICES.

We regret to have to announce the death of Surgeon-Major R. Lewins, M.D. (Retired List), A.M.S., on the 22nd ult. He joined the Army as assistant-surgeon in 1842, became surgeon in 1854, surgeon-major in 1866, and was placed on the Retired List in 1868. He served with the 63rd Regiment in the Crimea, including the battles of Alma, Balaclava, Inkerman, and siege of Sebastopol (medal with four clasps and Turkish medal); and with the expedition to the North of China in 1860 in charge of the hospital ship *Mauritius*, and he was also present at the capture of the Taku forts (medal).

"Audi alteram partem."

OVER-OPERATING IN GYNÆCOLOGY.

To the Editors of THE LANCET.

SIRS,—As many of those who, like myself, listened with pleasure to the address with which Sir William Priestley opened the section of Obstetric Medicine and Gynæcology must have longed to (but of course could not then) discuss the burning questions dealt with in the address, I trust you will kindly find room in the columns of THE LANCET for some remarks thereon. In the first place let me ask, Is there, as Sir W. Priestley avers, over-operating in gynæcology? Is it not rather the fact that the surgery of diseases of the female pelvic organs has participated in the immense advance which has been made in recent years in the surgical treatment of disease in all other parts of the human frame? I feel sure the surgeons and obstetric physicians of this country will repudiate the words of Verneuil (which Sir W. Priestley quotes), in which he describes those who remove the ovaries or resect a slice of the œsophagus or stomach as indulging in a "sanguinary debauch!"

Sir W. Priestley states that a demand for less operating comes from across the Atlantic, and it is right that this should be so, as in America lacerations of the cervix uteri (no matter how slight) have so frequently been sewn up and the uterine appendages removed for neuroses that discredit has been brought on these operations; but I altogether refuse to believe that in this country such indiscriminate and unnecessary operating is ever indulged in. Sir W. Priestley speaks "of the tendency in the present day of the obstetric physician to invade the domain of the surgeon in reference to what may be called external operations" (I presume he means operating on the uterus and its appendages per abdomen), and he goes on to say "the College of Physicians will look

Digitized by Google

askance at the claims for the Fellowship of those of its members whose chief work is avowedly surgical"—that is to say, that an obstetric physician may operate as much as he likes from below: remove fibroids, cure fistula, extirpate the uterus and ovaries per vaginam as hitherto, but once let his knife wander above the level of the mons veneris, even though he feels convinced he can save his patient more surely than by operating per vaginam, he puts himself outside the pale—the Fellowship of the College is not for such as he. This statement, Sirs, is such a serious one that in the interests of many present—and of all future—obstetric physicians, it surely calls for some definite ruling on the part of the authorities of the College. Of all the obstetric physicians and assistant obstetric physicians in London and the provinces there are, I believe, only five who do not perform abdominal section; of the five one was a very successful ovariotomist until the claims of an extensive midwifery practice caused him to cease doing these operations; two are prevented by the rules of the hospital to which they have become attached from continuing to perform abdominal sections; and the remaining two have, I believe, never so operated.

Sir W. Priestley suggests that those obstetric physicians who perform abdominal section should take the Fellowship of the College of Surgeons; but as one who possesses this valuable diploma I would respectfully point out to the president and council of the Royal College of Physicians that if they refuse the Fellowship to obstetric physicians who operate on the female pelvic organs per abdomen, and give it, as has been done for many years, to those who operate per vaginam, a grave injustice will be inflicted on many gentlemen who, on becoming obstetric physicians, looked forward to being made Fellows of their College in due course, provided they had done nothing derogatory to the dignity of the profession. By all means, if it is thought desirable, let it be a law that *in future* obstetric physicians who perform abdominal section shall not be eligible to become Fellows of the Royal College of Physicians, but in common justice let such law not be retrospective. Sir W. Priestley asks: "Are our antiseptic methods a sufficient safeguard against the possible contamination of lying-in patients by one who undertakes extensive surgical work in addition to obstetric practice?" I answer emphatically "Yes; and a man who has operated on a pyosalpinx or a suppurating ovarian tumour can, in a quarter of an hour, make it perfectly safe for him to attend a lying-in woman." Let me ask Sir W. Priestley this question, "Which is more likely to keep himself aseptic, the obstetric physician who performs abdominal section, and who from the very fact of doing these operations is imbued with the profound importance of keeping himself and all his paraphernalia aseptic, or he who does not so operate, but who may at any moment have to attend a midwifery case soon after examining a patient suffering from a stinking vaginal discharge?" The solution of the difficulty as to the obstetric physician operating Sir W. Priestley finds in "appointing a gynæcological surgeon to every hospital, who shall work in conjunction with the obstetric physician." If by this he means that every disease of the female peculiar to her sex (caruncles, polypi, vaginal cysts, uterine cancer, &c.) may be diagnosed by the physician, but must be handed over to the surgeon for operation, then I say that no obstetric physician of repute will hold office under such conditions; but if he means that the obstetric physician may (as at the Samaritan Hospital) do whatsoever operation he likes per vaginam, but must pass on all cases requiring abdominal section to the surgeon, then I say that in my humble opinion it is a case of "straining at a gnat and swallowing a camel." For my part I agree with what Dr. Herbert Spencer of University College Hospital said in a paper which he read before the Medical Society, that it would be a wise and gracious act on the part of the surgeons in every hospital to hand over to their obstetric colleagues all the cases of disease of the female generative organs requiring abdominal section; this has, I believe, been done for some years at King's College Hospital without friction between Dr. Playfair and his surgical colleagues. In conclusion, let me repeat now what I said in the discussion on Dr. Spencer's paper: "As the art of obstetrics is in great part surgical, those who practise that art should be called obstetric surgeons, that the qualification for holding such a post at a hospital should be the F.R.C.S. and not the F.R.C.P., and that the existing anomaly was the fault not of the College of Physicians, but of the College of Surgeons, which in years gone by refused to shelter under its wing the obstetrician." Apologising for the length of this letter, I am, Sirs, yours faithfully,

Harley-street, Aug. 3rd, 1895. WILLIAM DUNCAN.

"SPECIALISM IN MEDICINE."

To the Editors of THE LANCET.

SIRS,—The growth of knowledge has rendered "specialism" necessary. There was a time when the surgeon could compass all knowledge, not only of medicine and surgery, but also of hairdressing. Now only a Crichton could master the facts of the various divisions of medicine and surgery, including ophthalmology, gynæcology, dermatology, laryngology, otology, bacteriology, and the dozens of other "ologies" pertaining to medical science. I agree, however, with the leading article in THE LANCET of July 20th when it says that practical experience of general medicine is advisable and necessary before a special branch can be adequately dealt with. Unfortunately, it is becoming common for young men to study a subject with special industry before qualification with a view to the beginning of practice at once in that subject only. To start on a professional career in this manner is likely to result in practice of a one-sided and narrow character. These infant specialists have no doubt studied the various branches of medicine in which they are examined for their diplomas. But even this moderate knowledge of general medicine will be below that of the average newly qualified man on account of the undue attention given to their selected special subject. Starting practice, then, with even less than the average stock of general knowledge, and looking at everything with the coloured glasses of their speciality, how defective must be their apprehension and treatment of disease. On the other hand, he who has devoted some years of his life to general practice will see the inter-connexion of the general and special diseases, and of the latter with each other, without which knowledge no special branch can be satisfactorily practised. Nothing else can supply this training and insight, and the want of it gives a bias and narrowness that is the cause of most of the abuse of specialism in those that take it up from their medical birth. Otherwise it is liable to abuse as much, and no more, than the practise of general medicine. It would be well if no one started in special practice without having had ten years' experience in general work. I am, Sirs, yours truly,

July 31st, 1895. A SPECIALIST.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Action against a Surgeon.

AT the present Warwickshire Assizes an action was brought by Charles Stevenson against Dr. Eagar of Stourbridge to recover damages for alleged negligence. The plaintiff had an accident which resulted in a dislocated shoulder, which it was alleged had not been properly attended to. There was skilled professional evidence on both sides as usual. It was admitted that the plaintiff was subject to epileptic attacks, and the defence asserted that any subsequent injury found arose from this cause. The verdict was given for the defendant, Dr. Eagar, who may be congratulated upon having cleared himself from the imputations made upon his character and his skill.

Bank Holiday.

The exodus of a large number of inhabitants of the large towns at this season of the year is growing to an enormous degree. In this town the present time has broken record in the enormous number who have availed themselves of cheap excursions for short periods. And yet the advantages must be mixed with some alloy of risk to health. Packed in close railway carriages, deprived of natural rest by night travelling, and subject to all the inconveniences and dangers of inclement weather, it may well be remarked that these English people take their pleasure sadly. The consequences follow these disturbed conditions of ordinary life in disorders of nutrition and exposure to wet and cold. If the demand for excitement and change continues at the same rate of progress some alteration must be made in the usual railway arrangements, or some measures taken to make the holidays less universal. Appointing different seasons to various localities

Digitized by Google

as bank holidays would obviate much of the disorganisation which now exists.

The Hospital Saturday Fund.

Already the administrators of this fund have begun to make arrangements and anticipate the wants of the coming year 1896. A steady increase of the amount asked for year by year has taken place, and now a penny a week from the workmen of numberless establishments is sought for. In view of all the advantages offered by the Hospital Saturday Fund—admission to the convalescent homes, nurses in case of sickness at home, and surgical appliances and instruments—this cannot be considered too much to ask for. Nor does this refer to the contributions of women or boys employed at the various workshops and manufactories. The amount of £13,500 is put down as the requirements of the succeeding year, and active efforts will be made to obtain it.

Aug. 6th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Ancoats Hospital.

THE annual meeting was held on Wednesday last, Sir W. H. Houldsworth, M.P., occupying the chair. Founded in 1828, and containing something over 100 beds, it has done much good work in a poor neighbourhood. But the report, as is too often the case, speaks of increasing work with an increasing adverse balance at the bank. The total receipts for the year were £4174 19*s.* 2*d.* The expenditure was £5347 1*s.* 11*d.*, leaving a deficit of £1172 2*s.* 9*d.* During the past two years the adverse balance had increased by £262 16*s.* 4*d.* The medical report showed increasing demands on the out-patient department. Sir W. Houldsworth mentioned that a legacy of £600 had been left to the hospital by the widow of the late Bishop Fraser. He said he believed more hospital accommodation would have to be provided in Manchester, and "he was convinced that the future solution of the question would not be the extension of any one hospital, but it would be the establishment of local hospitals in various parts of the city close to the people who required them." This opens such questions as the increased cost of administration, with a falling-off in funds, and the provision of skilled physicians and surgeons, and the further question of their position and status. Are they to be what is called "pure" physicians and "pure" surgeons, and, if so, are they to live on their professional incomes, or will the staffs be formed from the neighbouring general practitioners?

Manchester Grammar School.

This ancient school had its speech-day on the 31st ult. in the Free Trade Hall. Mr. King, the high master, presided. He said that Sir Frank Lockwood, the chief name on their list of honours for this year, had promised to attend and give an address, but was unable to do so. There was a long list of old pupils who had achieved distinction, and the honour list showed that the school had this year obtained eight open and three close scholarships at Oxford and Cambridge. "The honours won by former scholars of the school afforded fresh evidence, if evidence were needed, that from an industrial centre like Manchester they could send some to tread the paths of literature and scholarship. E. T. Whittaker had won the Sheepshanks Astronomical Exhibition at Cambridge, and had also been bracketed second in the mathematical tripos. This was the third time in the last five years that the Second Wrangler had been an old Mancunian ..... No fewer than ten scholarships at Owens College had been won by grammar-school boys." In addition to these, five science, six commercial, and three art scholarships and exhibitions offered by the Lancashire County Council and the Manchester Corporation had been won by grammar-school boys.

Manchester Museum, Owens College.

Some short time since the Museum Committee memorialised the Corporation for aid in its maintenance, there being an annual deficit of £1200. The Museum was visited on May 2nd by the Free Libraries Committee, and they were much impressed with its admirable arrangement and great value as an educational agent. The committee considers this claim reasonable, but as the Museum is open to, and used by, many who are neither residents nor ratepayers of Manchester, it thinks it may be expedient for the Museum authorities to invite the co-öperation of other neighbouring corporations and county and district councils. The committee recommend a grant of £400 a year to be made out of the public libraries rate, on condition that £800 a year be obtained from the Lancashire and Cheshire County Councils and from local district councils. The report of the committee is to be considered at the City Council to-morrow, where it is to be hoped the memorial will be favourably considered.

Child Paupers and Potato-pie.

This subject still affords matter for discussion among the Salford guardians, one of whom at their last meeting reported a diminution in the thickness of the crust from 3 in. to 4 in. to three-quarters of an inch, "which was a great improvement." Though fit for children aged from nine to fifteen, he agreed with the medical officer that it was unfit for those aged from three to five. The chairman thought paste three-quarters of an inch thick was not fit for young children, with which opinion most of us would agree. It was not stated that they were to have some other delicacy instead of it. The medical officer is said to be dissatisfied still with the pastry, which he may well be, if it is to be the food of children aged from three to five.

Aug. 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh University Graduation Ceremonial.

THE graduation ceremonial in medicine at Edinburgh took place last week. The degree of Doctor of Laws was conferred upon two medical men. One of these was Dr. Thomas Edmonstone Charles of Rome; the other Dr. S. Weir-Mitchell of Philadelphia. Both these gentlemen were presented in appropriate speeches to the Vice-Chancellor by Sir Ludovic Grant, who pointed out that they might serve as a bright example and encouragement to those who were receiving degrees that day at the termination of a successful student career. Thereafter a large number of Doctors of Medicine and Bachelors of Medicine were introduced and officially capped. Professor Greenfield delivered the address to the graduates, congratulating them upon their achievements and urging upon them to do their utmost to promote the renown and success of the University and to increase its material prosperity. He alluded to the fact that in spite of the noble buildings the part devoted to pathology had not been completed and was devoid of the accommodation and appliances essential to the most important part of pathological research. From this the lecturer turned to matters affecting the graduates themselves, and concluded by an eloquent exposition of the proper relations that should exist between a medical man and his patients.

New Hospital Site for Edinburgh.

The Leith Corporation have had a request from the Edinburgh authorities for ground on which it is proposed to erect a temporary hospital in room of the hospital which is to be removed from the Queen's Park. Some technical difficulty regarding the ownership of the land having arisen the Leith authorities have decided to delay consideration of it.

The School of Medicine of the Edinburgh Royal Colleges.

As was mentioned in THE LANCET some weeks ago a scheme was on foot to more closely affiliate the extra-mural medical school in Edinburgh to the Royal Colleges. This, it is understood, has now passed its final stage and been accepted by the colleges. The governing body is to consist of fifteen members, five of whom are elected by the Royal College of Physicians, the Royal College of Surgeons, and the Association of Lecturers respectively. It is to exercise supervising and disciplinary functions. The school is to be called the Medical School of the Royal Colleges.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Brutal Outrage in Belfast.

A BRUTAL case, such as rarely occurs in Ireland, has occasioned a good deal of comment in Belfast. It seems that on Saturday, July 20th, a woman was found lying in a field on the Shore-road; she was thought to be the worse for

Digitized by Google

drink and was taken to the police-office where she was kept for eleven hours in the cells and was then seen by one of the police surgeons who sent her on an outside car to the Union infirmary. She was at this time very weak and almost senseless, and died on the evening of the day she was removed to the infirmary. It was found after death that she had received several wounds of the vagina, inflicted apparently by some instrument, and this had occasioned external bleeding and extensive subperitoneal hæmorrhage, so that she died from shock and hæmorrhage the result of brutal violence. The coroner at the inquest having commented on the case, the jury returned a verdict that she had died from shock and hæmorrhage the result of injuries to the genital organs forcibly caused by some persons or person unknown, and they strongly recommended to the responsible authorities (1) that a female attendant should be placed in the police cells; (2) that a proper room should be provided for prisoners in a sick or weak condition; (3) that the cells should be properly constructed; (4) that means should be provided for conveying sick prisoners to the hospital other than by an outside car; also that the police did everything possible for the deceased woman while under their charge; and that the coroner be requested to bring the foregoing recommendations under the notice of the Police authorities. No person has, up to the present, been arrested as the perpetrator of this abominable crime.

High Death-rate in Belfast.

At a meeting of the Belfast City Corporation, held on Aug. 1st, the report presented by the medical officer of health showed that the health of the city of Belfast was in a most unsatisfactory state, the death-rate for the four weeks ending July 20th being 28·2, while in the corresponding week of last year it was only 20·7. The deaths from all causes are very much in excess of what they should be at this season of the year. The deaths from zymotic diseases are 50 per cent. more, and those from chest affections 30 per cent. more than in the corresponding period of last year. The deaths from typhoid fever and diarrhœa and the infantile mortality have all increased. Various reasons may be assigned for the present very high death-rate (greater than Dublin city, Cork, Limerick, or Londonderry), such as the late wet and changeable weather; but it is quite evident that there must be some serious defective sanitary conditions in the city of Belfast to account for such an abnormally high death-rate. How is it that the death-rate of London keeps so low, and as years go past is actually getting lower? The present high death-rate of Belfast demands the most serious attention.

Improvements at the Belfast Royal Hospital.

At a special meeting of the Corporation of the Belfast Royal Hospital, held on Aug. 5th, it was decided to make some very necessary improvements, which will cost probably about £1500. It is contemplated first, to add to the present sanitary block so as to provide space for additional baths. These would add greatly to the comfort of the patients as, at present, their only baths are situated on the ground floor. The next improvement was the enlargement and rearrangement of the present theatre, and the addition to it of an adjoining room. For some time the staff have felt themselves very much hampered, particularly during the time students are attending, by the small size of the operating theatre. In addition to its proposed extension it is to be thoroughly refurnished with every appliance which can render it aseptic and in accordance with those rigid requirements now demanded by modern surgery. Instead of the present isolation wards it is proposed to erect a long range of one-storied buildings, with a large ward for males and one for females, the kitchen, sculleries, and pantries being in the centre, and at one end a mortuary, post-mortem room, and other required conveniences.

The Belfast Dispensary Committee.

At the monthly meeting of this committee, held on Aug. 5th, Mr. Isaac Dundee was unanimously appointed medical officer of Carnmoney dispensary district in place of Mr. J. Dundee (resigned).

Queen's College, Belfast.

The following is the list of prizemen at the close of the summer session:—Botany: senior, W. A. Price; junior, John Adams, William M. Hunter, and Marriott R. Rowan, B.A., Practical Chemistry: Isabel Addey Tate and William R. Beatty (equal), Arthur B. M'Master, and Galbraith H. Grills. Medical Jurisprudence: William J. Cousins. Systematic Pathology: David Fleck. Practical Pharmacy: James E. Whyte.

The Battle of the Clubs at Cork.

One of the local newspapers that had persistently supported the clubs in opposition to the demands of the Cork profession published a very ominous leading article last Thursday. It stated that as a vacancy for a medical officer had occurred owing to the death of Dr. O'Sullivan, the opportunity ought to be availed of by the clubs to see whether they could not come to terms with the profession, and a hope was expressed that the doctors would fairly meet the advances of the clubs. An admission was also made that the refusal of the Cork doctors to meet the imported medical men in consultation had proved very inconvenient in club circles. I can only say that all along the Cork profession simply demanded that persons requiring medical services who were in a position to pay should pay according to their means, and any proposal from the clubs based on that principle will receive every consideration.

Accusations against Union Infirmaries.

A shocking state of affairs was revealed at the last meeting of the Nenagh guardians. One of the guardians (Mr. O'Brien) stated, "I knew a respectable man to die at 9 o'clock at night on the infirmary floor and remain there till morning. That was not the only case of the kind. Another man fell down stairs and broke his neck. It is horrible to think of the treatment to which the infirmary patients have been subjected." The medical officer (Dr. Minnitt) endorsed that statement by saying patients "have been repeatedly picked up off the floors dead or dying." He added that he reported the fact, but no attention had been paid to his report. Those statements seemed to come by surprise on the guardians, and more than one stated that they had not previously been made aware of such a sad condition of affairs. As a result of the discussion it was decided to appoint paid nurses.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Italy and the British Medical Association.

FOR the moment Italian medicine finds its centre of gravity on the banks of the Thames, so full are her journals, professional and lay, of the cordial reception vouchsafed her representatives there, and more particularly of the impression created by Dr. Maragliano's paper, "Sulla Cura della Tubercolosi Col Siero Anti-tubercolare." From his chair of Clinical Medicine in the University of Genoa, and still more from his post of "*privat-docent* in General Pathology and Therapeutics with official bearing on Maladies of the Organs of Respiration," Dr. Maragliano has for some time set forth his views on the serotherapy of tuberculosis to an ever-widening circle of adherents both within and beyond the Genoese school. He has even had to appeal to the lay press to be relieved of the incessant requests for supplies of his serum on the part of votaries eager to put it in practice in the localities they belong to. But not till the 1st inst., when his paper was read at the Association meeting, has he developed his positions so broadly, so deeply, and with so determinate a bearing on cure. To his compatriots these positions are now for the first time accessible in the form finally conceived and set forth by their author, and while, in summarised fashion, they have been read with avidity in the lay journals enterprising enough to have them specially "wired" from London, they are to-day being mastered throughout the length and breadth of medical Italy, as given in the advanced proofs with which the *Riforma Medica* of Naples and some of the non-professional organs have been privileged. Italians I have always found extremely gratified by British appreciation, and when from the marked respect with which Professor Maragliano's paper was received they proceed to take note of the hearty "fratellanza" with which their compatriots, Dr. Angelo Mosso of Turin, or Dr. Salvatore Otolenglis of Siena (for instance), were welcomed, they recall the not less friendly reception accorded at past Association meetings to their lamented Pacchiotti and their happily still active Professor Celli of Rome, and are grateful for England's generous requital of the hospitality shown her sons at Padua and Bologna in years when Italy led the van of medicine in theory and practice.

Italian Hospitals.

One impression Italians never fail to bring back from such visits to the British Isles, and that is the vast superiority of the hospitals, say, in London or in Edinburgh or in Dublin (leaving those of the provinces apart) to anything they have at home or have witnessed even in Germany or France. On this subject Dr. Celli, Professor of Hygiene and *privat-docent* in sanitary police in the University of Rome, was particularly emphatic, after his intervention at the great International Congress of Hygiene and Demography held in London in 1891. THE LANCET gave prominence to his impressions at the time, but it was in Italy that they brought forth their appropriate fruit, and are still continuing beneficially to fructify. It is not too much to say that not a little of the hospital reform quietly and steadily being carried out in Italy is due to the lessons inculcated by Dr. Celli and his fellow visitors on their countrymen—reform at present revolutionising such great institutions as the Santa Maria Nuova at Florence and leading to the extended and improved accommodation, introduced, for instance, into the Ospedale Maggiore of Milan. In the former of these the abuses and defects, born of mediæval tradition, had come to be a public scandal, and are now being removed on a scale and with an energy sufficient to justify future notice in THE LANCET. Meanwhile I may in this connexion refer to the new Ospedale Umberto I., now advancing to completion at Monza, near the Royal residence, as an example of what kingly munificence, aiding modern medical science and architectural art, can accomplish. Covering an area of 44,000 square metres, and consisting of nine pavilions, it will include every appurtenance and appointment demanded by the most varied and refined methods, clinical and scientific, known to medicine and its practitioners.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Fire at Brest-Litofsk.

This summer has been one of the hottest of recent years in Russia. Hot weather is, however, not always an unmixed blessing in this country. One of the worst evils it entails is is the prevalence of fires in the forests and the destruction of villages and towns. An unusually large number of fires have occurred already this year. Several towns of considerable size have been almost entirely destroyed. The largest was the town of Brest-Litofsk on the borders of Poland, which contained 40,000 inhabitants, and which was burnt to the ground some eight weeks ago. Details of the disaster still occasionally appear in the press, and from these it appears that two hospitals, the Municipal and the Jewish, were destroyed by the flames; from the former all the patients were fortunately able to escape, but thirty-two of the patients in the Jewish Hospital were more or less severely burnt, some fatally.

Forthcoming Exhibition at Nijni Novgorod.

The exhibition to be held in Nijni Novgorod next year is, if one may believe report, to be on a very extensive scale. A great rush of visitors is anticipated and a large number of temporary hotels are being run up round the exhibition grounds to accommodate them. The authorities are therefore to be congratulated on having appointed a Special Commission to look after the sanitary arrangements of the exhibition and all connected with it. In addition to the local authorities who become members of the Commission the Government have appointed Professor Anrep as their representative. Professor Anrep is already well known in Nijni, as he was sent there by the Government in 1892 to take the necessary measures to meet the cholera epidemic, which was then rapidly spreading up the Volga.

Foreign Deputations in St. Petersburg.

A series of foreign missions or deputations have this summer visited St. Petersburg. The object of all has been the same, to offer congratulations to the Emperor Nicholas on his marriage and accession to the throne, and to pay a tribute of respect and sorrow at the grave of the late Emperor. The first to arrive was the Armenian mission, a purely ecclesiastical group, with the Catholicos Mekertich I. at its head. The Bulgarian deputation had also an ecclesiastic for its leading member—the Metropolitan Clement—but the rest of the members, seven in number, were laymen, and among them, senior to the others as regards actual years, was Dr. Mollog, a physician. The most picturesque deputation has been that from Abyssinia with Prince Damto at its head. There is no medical member of this deputation, as might have been expected; but among the followers of Colonel Leontief, whose (so-called) scientific expedition to Abyssinia has returned with the deputation, is the Archimandrite Ephraim, under which name is hidden the identity of a former medical practitioner, who was known to the world as Dr. Tsviétaief. He graduated Doctor of Medicine in the University of Moscow in 1859, and for many years practised his profession in Romanof-Borisogliebsk until some seven or eight years ago, when he joined the "black clergy"—i.e., became a monk.

The Cholera in Volhynia.

Volhynia continues to be the only Government in which cholera is present. The latest returns are as follows: between June 11th and 17th, 34 cases and 15 deaths; between June 18th and 24th, 59 cases and 10 deaths. The dates are according to the Old Style.

St. Petersburg, July 14th (26th).

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A Higher Grade of Educational Qualifications of Medical Students.

THE State Board of Medical Examiners of New York are deeply impressed with the inadequate knowledge of many of the candidates for licences who come before them. This board of examiners can endorse as sufficient to practise the licenses that have been issued by other State boards of medical examiners, provided their standards are not lower than those of the State of New York; and the sifting of standards has so shown up the altogether too low measure of acquirement that the board has adopted a resolution declaring that the interests of the public would be greatly benefited by requiring a higher grade of preliminary study before entering upon that of medicine at all. They recommend that the standard be so advanced that no student should enter a degree-granting medical school after 1897 who had not completed a full high-school course or its equivalent. The board finds that the standard is much lower in medicine than in any other profession; and it is a happy sign of the times that the public is waking up to the need of thorough training of the men to whom the care of the health of the people is to be entrusted.

The Estate of Dr. Oliver Wendell Holmes.

Dr. Oliver Wendell Holmes, the poet-physician, after really enjoying most of the truly desirable things in life, left an estate which is valued at $112,000. Much of it was the fruit of his gifted pen.

Exclusion of American Medical Inspectors.

It is reported that the Continental Powers will probably no longer allow the United States to place medical inspectors at their principal seaports to prevent the embarkation of emigrants infected with cholera bound to American ports. Such action of European Governments will prove a serious exposure of the United States to an invasion of cholera in the event of the appearance of that pestilence in Europe. The delegates from the United States Government to the International Sanitary Conference of Paris last year endeavoured to secure an international agreement on this subject. The conference, however, while admitting the importance of such an agreement, regarded it as not coming within the special objects of that conference, and advised that it be made the subject of another conference called for that purpose. Before the Paris Conference closed the United States delegates took the preliminary steps towards the calling of such convention.

Regulations of Attendance at Public Schools after Exposure to Infection.

The Pennsylvania board of health has just issued a set of instructions as to the time when teachers and pupils who have been exposed to the infective diseases may safely be admitted again to schools providing they continue in good health and have taken proper methods for disinfection. For

Digitized by Google

diphtheria after twelve days; small-pox, eighteen; measles, eighteen; chicken-pox, eighteen; mumps, twenty-four; and whooping-cough, twenty-one. Adults may be admitted at once if they disinfect their clothes and persons.

Density of Population in New York.

The recent census shows that in the last twenty-five years the population of the city has increased from 900,000 to 1,900,000. One million people, in large part formed of the poor and ignorant emigrants from Europe, have been added to our population. A certain acre near Essex and Stanton-streets having 622 people on it is the most crowded of any city in the world; but this maximum is nearly maintained for a whole square mile, including parts of wards, numbered 7, 10, 13, 11, 14, and 17. In this square mile there are gathered together 370,000 people, mostly aliens, whilst the enumeration of children under five years of age is 53,000. From the census returns giving the number of children of school age—that is, from five to fourteen years included—the estimated number in this square mile is 63,000. 50,000 should be in the primary schools, but there are in this whole square mile but 27,000 sittings in the primary schools, so that there are some 20,000 children more than can be received in the schools of this district.

July 30th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Election of the Staff of the Melbourne Hospital.

ON Aug. 15th the subscribers to the Melbourne Hospital will elect the honorary staff to hold office for the next four years, and the coming election is the great topic of the hour in Melbourne, exciting more interest than a Parliamentary contest. Cards and circulars from the competing candidates are scattered broadcast, and, go where you may, you are sure to be buttonholed and asked to vote and use your influence for some candidate or other, or asked your opinion as to so-and-so's chances of success. Most of the candidates have large election committees, who make it their business to see that every voter (of whom there are between 4000 and 5000) is interviewed on behalf of their candidate. All kinds of influences are brought to bear to secure votes. Nationality, religious creed, social position, everything but a man's professional qualification or fitness for the position or past services is a reason for giving him a vote. The whole business is a scandal which it seems hopeless to reform. The present and previous staff have supported measures to alter the system of election, but nothing is done, and every election is worse than the preceding.

The Macleay Bequest to the Sydney University.

The late Sir William Macleay left a sum of £12,000 to the Sydney University to found a chair in Bacteriology. The bequest was subject to certain conditions, one of which was that every student before being admitted to a science or medical degree must have attended a six months' course of bacteriology. The Senate of the University accepted the bequest, but difficulty arose as to the interpretation of a "science degree" and of "a course of bacteriology," and a friendly suit in equity was instituted, and Mr. Justice Owen construed "a science degree" to mean a degree in biological science, and "the course of bacteriology" to be an amount of lectures or teaching in bacteriology extending over such academic term as might from time to time be prescribed by the Senate. That body now finds that to carry out the bequest as thus construed entails the establishment of a laboratory and museum, and a large outlay which the University at present is unable to meet. A committee was appointed to investigate the question, and has reported that the Senate should sanction the return of the bequest to the executors of Sir W. Macleay's will. The money will then revert to the Linnæan Society to maintain a bacteriologist who will carry on bacteriological investigations and also take pupils.

The Maintenance of the Sick Poor in Sydney.

The report of the Medical Adviser to the Government, Professor Anderson Stuart, on the maintenance of the sick poor during 1894 has been presented to Parliament. The total number of applicants for relief at the King-street Hospital Admission Depôt was 8162, or 303 more than in 1894. Of these, 1677 received orders for the Coast Hospital, 668 for the Sydney Hospital, 693 for the Prince Alfred Hospital, 244 for the Moorcliff Ophthalmic Hospital, and 65 for the Carrington Convalescent Hospital; whilst 2308 were recommended for admission to the asylums for the infirm and destitute, 1976 received orders for outdoor treatment, 132 for trusses, and 399 were refused relief, not being fit subjects for aid from votes granted by Parliament. In addition to the patients dealt with personally at the Hospital Admission Depôt, 972 were admitted under Government orders to the Coast and Metropolitan Hospitals, and paid for in the latter institutions at the usual maintenance rate. These include patients found by the police and taken direct to the hospital, urgent cases of fever and other diseases reported at the Medical Adviser's office by registered medical practitioners and transfers from Government institutions and country hospitals for special treatment. The total number of applications for hospital treatment during the year was, therefore, 9134. The total cost of the patients in four of the hospitals was £13,171 9*s.* 4*d.*, apportioned as follows:—Prince Alfred Hospital, £4991 13*s.*; Sydney Hospital, £4095 12*s.* 10*d.*; Moorcliff Ophthalmic Hospital, £3045 10*s.* 6*d.*; and Carrington Convalescent Hospital, £1038 13*s.* Professor Anderson Stuart again calls attention to the necessity for a hospital for phthisical patients, especially for those in the incurable stages of the disease. He also refers to the want of an organisation for providing for the sick poor at their homes, as well as to the necessity of legislation to prevent the influx of persons who from the time of their arrival here become a charge on the State.

July 6th.

Obituary.

SIR JOHN TOMES, F.R.C.S. ENG., F.R.S., L.D.S.

WITH great regret we announce the death, in his eighty-first year, of Sir John Tomes, which took place at Caterham on Monday, July 29th. To his literary and political exertions dental surgery mainly owes its present position; indeed, he may fittingly be described as the Bismarck of his profession. He was the son of John Tomes of Weston-on-Avon, the Tomes family having settled near there and been in possession of a small property at Marston Sicca since the reign of Richard II. It was at Marston Sicca that Mrs. Lane, a kinswoman of the John Tomes of that time, assisted Charles II. to escape after the battle of Worcester by giving him shelter. Owing, however, to the entail being cut off, Sir John Tomes' father, though the eldest son, did not inherit the property, and it was always a source of great regret to Sir John Tomes that the old house had passed out of the direct line to an uncle of his. His father was a man of marked ability and artistic talent as well as a great reader, especially of metaphysical works, and was not until late in life in a position to do more than educate his sons, so that Sir John Tomes was wholly dependent upon his own exertions after his student days. He was the first member of his family to take to medicine, the study of which he began by being apprenticed to a general practitioner. In the year 1836 he came to London and entered at the Middlesex Hospital and King's College, and was a fellow student of Sir William Bowman. In 1839 and 1840 he acted as house surgeon to the Middlesex Hospital, and during this period he invented forceps adapted to the necks of the different teeth. It was, perhaps, this that determined his subsequent devotion to dental surgery. In 1842 he was appointed dental surgeon to King's College, but this post he subsequently resigned, and was appointed to a similar one at Middlesex Hospital. In 1845 he invented a machine for copying in ivory irregular curved surfaces, and was awarded the gold medal of the Society of Arts. This machine was intended to be applied to carve bone to correspond to a cast of the mouth. When, in 1846, Dr. Morton, a dentist in Boston, Mass., applied ether as an anæsthetic Sir John Tomes immediately took up the question, and administered sulphuric ether, and sometimes chloric ether, in the out-patient department for dental operations. In his diary on Jan. 14th, 1847, the following note occurs: "Gave ether to Arnott's case of lithotomy. Eight minutes and insensibility came; the operation was then commenced and lasted twelve minutes." And on Feb. 23rd: "Gave

Digitized by Google

ether to eight patients for operation with great success—Earl of Cadogan (a governor of the hospital) and many others present."

About 1845 to 1847 he delivered a series of lectures on Dental Physiology and Surgery, and these on being published at once brought him into note. In 1859 "A System of Dental Surgery" was produced, and it may truly be said that with the appearance of this volume dental surgery was placed on a scientific basis. He was one of the leading spirits of the educational movement which finally resulted in the establishment of a board of examiners in dental surgery by the Royal College of Surgeons of England and the granting of a diploma in dental surgery, and with Mr. T. Bell and Mr. A. Rogers he formed the dental portion of the first examining board. The curriculum established by the College mainly through his suggestions has worked so well that but few material alterations have been found necessary up to the present time, although the modes of examination have been considerably amplified. Sir John Tomes was amongst the founders of the Odontological Society, and twice occupied the office of President. He was an active supporter of the Dental Hospital of London from the first, and, in addition to occupying a position on its staff as dental surgeon, he filled the office of lecturer in dental physiology and surgery. But valuable as his political work thus had been, it was to a great measure overshadowed by the important part he played in 1878, when, with Mr. J. Smith Turner, he was mainly instrumental in obtaining the Dentist Act, and so placing the dental profession on a sound social footing. The essential clauses of the Act were prepared under his guidance, and mainly by his influence was opposition overcome until it became law. In the formation of the British Dental Association he took an active part, and occupied the presidential chair at the first annual meeting, which was held in London during the year 1881. As a scientific anatomist Sir John Tomes earned great distinction, and by his researches dental anatomy was largely enriched. By the discovery of the protoplasmic nature of the dentinal fibril the commencement of the proper understanding of the nature of denture commenced, and this must always rank as his greatest contribution to dental science. With the late Mr. C. de Morgan he carried on researches into the minute anatomy of bone, and these were published in a paper contributed to the Transactions of the Royal Society. His contributions to the study of comparative anatomy were many, including amongst others the following: "On the Structure of the Teeth, the Vascularity of those Organs, and their Relations to Bone"; "Structure of the Dental Tissues of the Order Rodentia"; and "On Dental Tissues of Marsupialia." How great a loss the dental profession has sustained it would be difficult to say, and although he had retired from active practice for some years, nevertheless, in all subjects his opinions were eagerly sought for by those in whose hands the future of dental progress mainly lies. Only last year Sir John Tomes celebrated his golden wedding, and the occasion was commemorated by the members of his profession founding a prize bearing his name, which has been placed under the custodianship of the Royal College of Surgeons of England.

JOHN THOMAS REESE, L.F.P.S. GLASG.

WE regret to announce the death of Mr. John Thomas Reese, surgeon, of Ystradgynlais, in the Swansea Valley, which occurred on Sunday, July 21st. Mr. Reese was on his way, which lay across a mountain, to see a patient, when he was struck by lightning and with his horse instantly killed. Mr. Reese had practised in the neighbourhood for eighteen years and was universally popular. He was buried in the presence of some 3000 friends on Wednesday, July 24th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. S. Moos, Professor of Otology in Heidelberg.—Dr. Kiener, Professor of Pathological Anatomy in Montpellier.—Dr. Baillon, Professor of Medical Natural History in the Paris Faculty of Medicine.—Dr. Albert Nagel, Professor of Ophthalmology in Tübingen, quite unexpectedly, in his sixty-third year. He was born in Dantzig, and was one of the first pupils of Albrecht von Graefe.—Professor Moos, the Otologist at Heidelberg, at the age of sixty-four.

THE BRITISH MEDICAL ASSOCIATION.

MEETING IN LONDON.

AT the end of the general meeting on Thursday last Sir J. Russell Reynolds desired the members to stay for the consideration of the proposed memorial to the late Professor Huxley, and introduced Professor Michael Foster, Secretary of the Royal Society, who stated that steps were being taken to raise a memorial to Professor Huxley on as broad a basis as possible, but that, owing to the lateness of the season, it had been thought desirable to defer active steps until after the autumn recess. No attempt had been made to determine in any way the nature of the memorial, which must depend upon the amount received, but a provisional committee had been formed, and he trusted that the medical profession of which Professor Huxley was a member, which he loved and which whenever he could he helped, would desire to join in this effort to perpetuate the memory of so great a man. Sir John Lubbock had consented to act as treasurer to the committee and subscriptions might be sent to him, and Professor G. B. Howes, of the Royal College of Science, South Kensington, as one of the secretaries to the committee, would be happy to receive names and answer inquiries. Dr. Ward Cousins, the President of the Council, said he felt sure that the whole of the profession would respond warmly to the effort to produce an adequate memorial.

The annual dinner of the Association, which was held at Queen's Hall, Langham-place, on Aug. 1st, was a decided success. Covers were laid for 700 guests, not only the floor of the hall but the grand tier also being crowded with tables prettily decorated with roses and evergreens. While the guests were assembling the string band of the Royal Engineers played a selection of music. Sir J. Russell Reynolds presided, and among some seventy-five invited guests were the Lord Chancellor, Lord Herschell, the Lord Chief Justice, Mr. Christopher Heath (President of the Royal College of Surgeons), Professor Stokvis (Amsterdam), Dr. W. W. Keen (New York), Sir Wm. Flower, Professor Bowditch (Boston), Professor Mosso (Turin), and Dr. Fraenkel (Berlin). The speeches were almost as brief as the grace, *Benedictus Benedicat*. "The Queen" and "The Royal Family" having been honoured, the President proposed "Our Guests," and Lord Halsbury, in responding, by a *lapsus linguæ* created some merriment in which he heartily joined, although it was against himself. "I am yoked," said the Lord Chancellor, "with four other 'distinguished' guests." Professor Stokvis followed with a happily conceived speech, full of thanks to the Association and praises of the medical profession in England. Dr. Keen convulsed the assembly by describing a case of heredity in which the succeeding generations of a man who had undergone an operation where Murphy's button had been used produced a child "with a long row of buttons ....." The conclusion of the sentence was lost in the burst of laughter which followed. Mr. Christopher Heath also spoke. "The British Medical Association," coupled with the name of Dr. Ward Cousins, was proposed by Sir George Young; and "Our President," proposed by Sir William Priestley, and responded to by Sir J. Russell Reynolds, brought a pleasant evening to a close.

The Masonic Smoking Concert, given on Thursday, Aug. 1st, in the Portman Rooms, Baker-street, in honour of the Medical Freemasons who attended the meeting of the Association, proved to be a very happy thought on the part of the hosts, the Æsculapius Lodge and Chapter, No. 2410,

Digitized by Google

and was a distinct success. The programme contained the names of forty-four well-known artists from the theatres and music-halls, most of whom put in an appearance. It is impossible to repay their kindness in entertaining medical Masons by mentioning all their names, but it may be noted that Mr. Arthur Roberts met with quite an enthusiastic reception, Mr. Lionel Brough told tales—some with a "medical" flavour—in his own dry humorous way, Miss K. Seymour and Mr. F. Wheeler gave the admirable Japanese dance from *The Shop Girl*, and Mr. Charles Godfrey an impersonation, and eulogistic song recording the achievements, of Mr. W. G. Grace in the cricket field. The programme was not exhausted until past one o'clock, when the proceedings terminated with a hearty vote of thanks on the part of the visitors to the members of the Æsculapius Lodge and Chapter for their hospitality and entertainment.

On Friday evening, the 2nd inst., the Council of the Royal College of Surgeons of England gave a very successful conversazione at the College in honour of the meeting of the British Medical Association in London. A very large number of guests attended, and the presence of ladies added greatly to the brilliancy of the scene. The visitors were received in the Museum by the President, Mr. Christopher Heath, and the Vice-Presidents. There were many very interesting exhibits. In the council-room was shown the diary of a Resurrectionist for a little more than a year in 1811 and 1812, giving details of the bodies raised; also the books of the Corporation of Surgeons, containing, in December, 1758, an entry showing the name of Oliver Goldsmith examined for certificate as "hospital mate" and found "not qualified"; a number of daguerreotypes, taken in the early forties and presented recently to the College by Mr. Jabez Hogg; the portraits include several eminent physicians and surgeons. In the library committee-room were shown the Hunterian relics belonging to the College, including an escritoire, a study table, and several instruments belonging to Hunter. In the same room was exhibited a series of drawings made by W. H. Clift of the heads of murderers brought to the College after execution for dissection; among them was a drawing of Bishop, who was concerned with Hare in killing an Italian boy for the purpose of selling the body for dissection. The London Welsh Glee Singers gave performances in the theatre at intervals, and in a part of the museum the string band of the Royal Engineers played a selection of music.

On the same evening the Royal College of Physicians of London were at home to the members of the Association in their quaintly stately home in Pall-mall. The architectural beauty of the building, the perfectly proportioned rooms, the interesting and, in some cases, splendid pictures and the unique reliques, ever make of the College an admirable place of reunion, and the numerous guests of the President and Fellows appreciated the hospitality to the full. The floral decorations were particularly brilliant.

An interesting discussion took place in the Obstetric Section on the Early Diagnosis of Malignant Disease of the Uterus and the Treatment by Partial or Total Excision. With reference to the first point, we think the duty of the profession is twofold—first, to insist on a thorough examination in any suspicious case, especially when the patient is near the menopause; and, secondly, to educate women (as Dr. Scharlieb so well pointed out) not to neglect to report to their medical attendants the existence of any abnormal discharges, specially when these occur at the climacteric period. The general feeling of the speakers who took part in the discussion was against placing great reliance on microscopic examination as an aid to diagnosis, though it is only fair to state that it is a question whether in England such a thorough pathological examination is carried out as is done in Professor Martin's clinique at Berlin. Of the early clinical signs of malignancy probably hæmorrhage occurring after an examination, as well as the peculiar sensations conveyed to the educated finger, are of the greatest value; but the symptom mentioned by Professor Japp Sinclair of Manchester is also worthy of attention. He says in a doubtful case if on using a sharp spoon the parts, owing to their friability, break down, leaving a cavity, cancer is indicated. In a non-malignant case the curette causes no excavation. As to the treatment, there can be no question that the opinion of the great majority of the speakers was strongly in favour of total removal of the uterus when the disease was limited to it. In England, perhaps owing to our natural conservatism, and, as some of the speakers pointed out, from the fact that in the early history of the operation the mortality was high, some surgeons still advocate the partial excision; but with a greatly improved technique and a very much lowered mortality the method of total removal has received universal recognition in all parts of the United Kingdom. We must not forget, however, the very important fact that after any method the disease may reappear. Professor Pozzi's statement is (from his very great experience) of the utmost value. He said he had never seen a case lasting longer than three years after operation without recurrence. In this connexion, however, we may refer to six cases published in our columns by Dr. Lewers, in which, after supra-vaginal amputation of the cervix, the patients remained well after periods varying from two to eight years. The specimens were shown at the Obstetrical Society of London.

The subject set down for discussion in the Section of Pharmacology and Therapeutics on Thursday, Aug. 1st, was really rather too lengthy to be dealt with adequately in the time allotted to the various speakers. We refer to the requirements of the profession with reference to the revision of the British Pharmacopœia. Dr. Leech, who opened the discussion, attempted to keep it within clear limits, and confined his remarks to the nature and extent of the list of medicines, the mode of preparation of compounds, the weights and measures to be employed, and the amount and extent of accessory information to be given, indicating also tests for purity. Dr. Donald MacAlister followed on the same lines, and thought the size of the Pharmacopœia might be reduced by the "avoidance of the superfluous." From this point, however, many of the speakers found the time limit irksome, and although there was a general agreement that simplification was desirable and that it was quite consistent with accuracy, there was obviously a tendency to review the Pharmacopœia in detail rather than to indicate broad lines of improvement. Dr. Tirard, however, brought matters back into the proper channel by the narration of his experiences as secretary to the Therapeutic Committee of the Association; while Dr. MacAlister was responsible for the important statement that the Pharmacopœia Committee of the General Medical Council had already decided upon the introduction of the metric system of weights and measures alongside of the English system.

The organisers of the various entertainments and excursions deserve great praise for the admirable manner in which these functions were carried out, and no one with the excellent little local guide before him or her, as the case might be, could fail to find both instruction and amusement in the ample programme provided. During the week there were several excursions to places of interest more or less near to the metropolis; but by

Digitized by Google

far the best series was reserved for Saturday when members could spare a whole day to pleasure. A party of some 200, including ladies, visited Epping Forest and Claybury, where they inspected the London County Asylum. By the invitation of Mr. Hutchinson, President of the Royal Medical and Chirurgical Society, many members visited his country seat near Haslemere and partook of lunch with him in the new Museum. The Oxford, Reading, Maidenhead, Windsor Castle, and Hampton Court excursions were chosen by other parties, and the Hastings and Eastbourne trips were well attended. The medical practitioners of the first-named town invited 150 of the members of the Association to visit them, and the various local excursions in which the Hastings medical practitioners acted as guides were much appreciated.

In spite of the unpropitious state of the weather on Saturday last those members of the Association who took advantage of the hospitality offered by the Eastbourne Medical Society had every reason to congratulate themselves upon their choice of this excursion among the many to choose from. At the town hall a most sumptuous lunch was provided and the party were cordially received by the Mayor, Councillor Skinner, and the President of the Eastbourne Medical Society, Mr. J. H. Ewart, who presided, at the luncheon. The health of the Association was enthusiastically honoured, and responded to by Mr. R. O'Callaghan and Dr. More Madden. The party were then taken for a drive of about twenty-five miles, including a visit to Beachy Head, Birling Gap, and Wannock Glen, where a fruit tea was enjoyed by the party after their long drive.

We understand that the Mayor of Eastbourne has given a pressing invitation to the members of the British Medical Association to hold their next annual meeting in his borough, and has requested Mr. O'Callaghan to lay the matter before the Council.

The debate on the subject of the increase of direct representatives at the second general meeting was concluded more moderately than at one time appeared likely to be the case. In the end a resolution by Dr. Rentoul was passed instructing the Council to demand that the registered medical practitioners of England shall be empowered to elect five more direct representatives, the practitioners of Scotland one, and those of Ireland one more than at present. Dr. Hugh Woods diagnoses senility and decay in the present General Medical Council, and looks confidently to the time when it will elect all the members. There is such a thing as being too acute in diagnosis, from which error false prognosis is apt to arise. If there is any chance of increase in the direct representation—and we think such increase is decidedly called for, and might perhaps be balanced by grouping the smaller bodies that are more favoured with individual representation—it will be hindered rather than helped by all extreme views.

We hope to complete our reports of the proceedings in Sections next week, but the many interesting discussions have required at our hands more detailed treatment than on previous occasions. The meeting of the British Medical Association of 1895 has been a scientific success, for if no startling theory has been promulgated, or at any rate, made good, the orderly and useful debates upon practical topics were conducted on the lines that lead to progress while consolidating present knowledge.

We desire to record our sense of the invariable courtesy extended to us by the officials of the Association, and to our representatives by the honorary secretaries of the various sections.

THE GENERAL MEETINGS.

THE CONCLUDING GENERAL MEETING.

THE final general meeting was held at Exeter Hall on Friday afternoon, Aug. 2nd, when Professor SCHÄFER, Jodrell Professor of Physiology in University College, London, delivered the address in Physiology, which we print in full in this issue.

Sir J. RUSSELL REYNOLDS, in introducing Professor Schäfer, referred to him as his friend, his old pupil, and his colleague. At one time, said the President, he was the great friend and almost the physiological godchild of his old master, Professor Sharpey, the greatest of all teachers that have been honoured in England. For many years before he died Professor Schäfer assisted him at University College. At the meeting of the Association in 1873 Professor Sharpey delivered the address in Physiology, "and a remarkable address, too, it was," concluded Sir J. Russell Reynolds. After the delivery of the address,

Professor BOWDITCH of Boston proposed a vote of thanks to Professor Schäfer. This was seconded by Dr. LAUDER BRUNTON and heartily accorded.

Votes of thanks to Her Majesty the Queen and other members of the Royal Family for the interest and practical sympathy they had shown in the proceedings of the meeting of the Association; to Mr. Andrew Clark, Dr. Isambard Owen, Mr. H. T. Butlin, and others who had been active in organising the meeting; and to Sir J. Russell Reynolds for his able conduct in the chair, brought the formal proceedings of the sixty-third meeting of the British Medical Association to a close.

MEDICINE.

WEDNESDAY, JULY 31ST.

Discussion on Diphtheria.

Mr. LENNOX BROWNE, referring to Dr. Martin's experiments on animals, criticised those dealing with the increase in weight, or, at any rate, stated that they did not fully agree with those made by other observers. As regards nephritis, he had found that it had occurred in 9 out of 27 deaths in the 100 cases that he had followed—that is, in all of those cases in which permission to make a post-mortem examination had been obtained. He wished it to be noted that Dr. Goodall said that antitoxin does not protect against diphtheria, and thought it must be borne in mind that the injection of antitoxin simultaneously with the poison could scarcely be followed by the same results as when the poison had had some start. He differed from those observers who held that serum was most useful in cases of pure diphtheria, as he had found that the serum was really most useful in mixed cases. He wished to show that there were fallacies in Dr. Goodall's statistics of cases examined during the twelve months and to point out that only 110 of these had been bacteriologically examined, whilst no note was made as to the conditions in 109. A mortality of 21·9 did not afford much evidence that this remedy was of much value, whilst it should also be observed that small doses only of the antitoxin were given in the early cases, and that consequently these could scarcely be reckoned amongst those treated with antitoxin. Finally, he maintained that all the results which had been obtained by the antitoxin treatment might be obtained in the hands of those who carried on most perfectly what might be spoken of as the classical treatment; in fact, the only statistics that were worth anything were those in which the antitoxin treatment could be compared with the best classical treatment. As regards the statistics published in the *British Medical Journal* he would point out that in about two-thirds of the cases mentioned there had been no bacteriological examination, and it appeared to him evident that the whole of the improvement in the case mortality might be attributed to the improved hygienic conditions under which the patients were placed.

Professor BAGINSKY (Berlin) said that as one of those earliest in the field in using antitoxin—which had been prepared by his assistant, Dr. Aronson—he had been able to observe a large number of patients most carefully. He had a record in all of 710 cases. Amongst the 525 cases treated up to March he had had a mortality of 15·6 per cent., against a mortality for the preceding four years of 41 per cent., or for the year 1893 of 58 per cent. Coming to the age mortality, he found that up to two-years of age the mortality was 63·36 per cent. without serum treatment, and 25·28

Digitized by Google

with serum treatment; between two and four, 52·85 without, and 17·12 with serum treatment; between four and six, 37·90 without, and 17·24 with serum; between six and eight, 27·41 without, and 11·39 with serum; between eight and ten, 19·35 without, and 5·00 with serum; between ten and twelve, 15·07 without, and 10·00 with serum; between twelve and 14, 13·00 without, and 13·00 with serum treatment. In his last 185 cases, since March, his case mortality had come down to 8 per cent., a sufficiently striking figure to compare with any statistics. He would like to point out to Mr. Lennox Browne that in his experience the whole character of the disease had changed under the antitoxin treatment. The patients look and eat better, and their whole appearance is markedly better than it was before. Disease of the heart is, of course, not done away with, whilst there were undoubtedly cases of mixed infection and septic cases which were extremely difficult to treat. As regards nephritis, he was at one with those who had observed it in a large percentage of cases before antitoxin was ever thought of, but he was convinced that the course of the disease under antitoxin treatment was less prolonged and of a much milder type than had previously been the case. He agreed with Professor Von Ranke that laryngeal stenosis is not of such frequent occurrence in cases that had been injected with antitoxin, and that it never occurs in the later stages of the disease as was formerly the case. One of the points that he wished to insist on was that the quantity of serum might in many cases be increased with advantage. Of those cases in which there had been laryngeal stenosis he had been able to obtain a recovery of 60 per cent., whilst previously to the use of this remedy the percentage of recoveries under otherwise similar conditions was only 21 per cent. Mr. Lennox Browne spoke of enthusiasm carrying them away; could that now be said to be the case?

Dr. SIMS WOODHEAD asked if it was to be a reproach against those who were working at the antitoxin treatment that they were enthusiastic. It was, he maintained, an enthusiasm that—in view of the number of experimental and clinical facts that had been brought before them that morning—was thoroughly justified. Dr. Martin's experiments, detailed and accurate as they were, and dealing with special points which could not but be of interest to those who were actively engaged in combating the disease, corroborated the interesting and valuable statistics that had been so clearly placed before them by Professors von Ranke and Baginsky, whilst he held in his hand a series of statistics recently published which he took the liberty of placing before them, as they afforded an additional link in the chain of evidence which was rapidly being forged in support of the antitoxic treatment of diphtheria. It was not always desirable to quote statistics which were not one's own, but those of M. Richet in the "Revue Scientifique" for July 20th were exceedingly striking, and he should take the liberty of summarising them. The actual number of deaths from diphtheria in Paris during periods of fourteen days were given for the first six months of a series of seven years—1884, 1887, 1890–1894. In this it was found that the lowest mortality during any one fortnight was 30, whilst the highest was 145. Coming now to the first six months of the year 1895, during which the antitoxic serum treatment was becoming generalised in Paris, it was found that the number of deaths in any one fortnight was 27, whilst the lowest was only 4. He thought that these figures by themselves were sufficiently striking, but when taken in conjunction with the statistics they had heard that morning and with the experiments that had been detailed, he thought that they afforded a basis of fact which would justify a considerable scientific enthusiasm. He had recently on several occasions said really all that he had to say on this question, and he did not propose at this late stage of the discussion to intervene between them and those who had a number of interesting facts to contribute, but he could not refrain from remarking that the experimental facts had been more than confirmed by clinical experience, and although he had not any clinical material which he could place before them, he wished to state that as one of those engaged in experimental work he was convinced that as physicians became less afraid of using full doses of antitoxin, better and better results would be obtained; he was exceedingly glad to hear, from the experience of Dr. Martin and of Professors von Ranke and Baginsky, that such also was their experience.

Dr. HERMANN BIGGS (New York) stated that since Jan. 1st any attending physician who applied for antitoxin at the office of the Health Department of New York, was supplied with it free of charge, and it was used along with an inspecting physician sent by the Board. He had not the data from which to give the case mortality for New York previously to the antitoxic treatment, but on comparing the reported cases he found that since this treatment had been introduced the case mortality had fallen at least 40 per cent. for the city as a whole. Dr. Goodall had expressed a doubt as to the immunising power of serum, but he had by him a number of statistics which he thought would throw some light on this subject. In one asylum in which diphtheria had been very frequently met with the whole of the children were immunised with 200 units each of Behring's serum, excepting in the case of very young children, who received only from 120 to 150 units each. There was an immediate cessation of the outbreak, and not one case appeared until the nineteenth day, when one patient had a mild attack. Then other cases occurred on the 30th and 31st, and during the following week 5 other cases appeared. The immunisation process was repeated, and from that date to July 15th only three cases occurred. That the infective material was still present was evident from the fact that three cases brought in and not immunised all took diphtheria, whilst in certain cases virulent Löffler bacilli were demonstrated as being present in the throats. In another institution there were 46 cases of diphtheria during fifteen or twenty days before the immunisation process was carried out, after which not one single child took the disease, but one of the nurses and the resident physician, who had not been immunised, were both attacked, whilst in the throats of 11 of the cases that had been immunised and which were examined for diphtheria bacilli, a positive result was obtained in six, but in none of these cases was there any outbreak of the disease. From this and other experiments he argued that the period of protection really extended over about thirty days. In none of the cases infected had there been any unfavourable symptoms beyond urticaria and slight morbilliform rashes which usually made their appearance about the ninth day after injection, whilst at the time of injection there was frequently a slight rise of temperature, so insignificant, however, as to call for little attention.

Dr. CAMPBELL HALL said that he came from a district in which diphtheria was endemic, and he must say that he had certainly not been disappointed by the antitoxic serum, but had been surprised and delighted by the results that he had been able to obtain. He found that after injection the membrane never spread and gradually but surely disappeared. So successful, indeed, had he been that he decided never to treat a case of diphtheria except with antitoxin, if that substance was at all procurable.

Dr. PAVY said that although this subject was of vast interest and great importance the time allotted to its discussion had already been exceeded, and they must now go on to the next subject on the programme.

The Treatment of Diabetes Mellitus by Uranium Nitrate.

Dr. SAMUEL WEST, Assistant Physician to St. Bartholomew's Hospital, read a paper on this subject. A short account was first given of the physiological action of uranium, of which, however, little is known except that in poisonous doses it acts as an irritant poison and ultimately produces albuminuria and also glycosuria. Diabetes having been selected as the disease in which to try the effect of the drug it was administered to a number of out-patients, and they all agreed in stating that their thirst was relieved, the quantity of urine reduced, and their general health improved. Then systematic investigations were made upon patients under close observation. Two cases have been under observation for over a year, and very frequent determinations of the urine made. The results have been set out in the form of tables or curves, upon which are indicated the times at which the drug was administered. The patients were all placed upon a fixed diet and under constant conditions, so that the only variation in their condition should be the administration or withholding of the drug. The first case was that of a young man aged 22. He was admitted into the hospital and placed upon the ordinary diet for three weeks or so before the drug was administered. This produced some improvement, and the percentage of sugar and the quantity of urine fell from an average of seven pints to five, the percentage of sugar also falling from about eight to between six and seven. On the administration of the uranium in small doses, gradually increased, the effect was first shown upon the quantity of urine, which was diminished considerably, falling from an average of five to

Digitized by Google

an average of three pints. The percentage of sugar also fell from about 5 to about 3. The drug was administered for about two months without intermission, being gradually increased up to fifteen grains three times a day. At the end of that time the percentage was about 1. The drug was then stopped for a time and the percentage of sugar rose again to about what it had been before—that is, between 5 and 6 per cent. Uranium was then re-administered and increased gradually. As soon as about seven or eight grains were being taken three times daily the percentage suddenly fell to about three, and with its continued administration it was finally reduced to under 1, indeed, under ½ per cent., where it remained for nearly four months, the patient having all this time gained health and weight, being nearly one stone heavier than when the treatment was first commenced. The drug was then given up again, and about Christmas time the patient did not seem so well, possibly in connexion with the festivities. The percentage was then found to be between 6 and 7, and shortly after this it actually reached 10 per cent. for one or two days. Uranium was administered again, and after about a month the percentage rapidly fell, and at last was again under ½ per cent. The quantity of uranium was reduced, the patient taking about five grains daily, and when he left the hospital a little later the percentage was between 2 and 3, but he was very well and much heavier than when he was admitted. He was not seen again till the autumn, after an absence of about four months, during which time he had taken no medicine. The percentage was then found to be again between 6 and 7, and uranium was once more administered. He was only seen from time to time, but within a month the percentage had fallen to 4. At Christmas time it rose again, and the uranium was given in fifteen-grain doses. A month later the percentage had fallen to a little over 1, and that was the condition when the patient was last seen. The second case, that of a woman of about forty-five years of age, was a private patient who had been under treatment for some time before uranium was administered. She was then passing about 1800 c.c. of urine and between 2 and 3 per cent. of sugar. Uranium was given and very soon the reduction in the quantity of urine was marked, the amount falling to about 1000 c.c. Later the percentage of sugar also fell to 1, and then under 1, and after the administration of the uranium for about two months the sugar entirely disappeared from the urine and remained absent, with one or two exceptions on odd days, for more than four months. At that time, though the uranium was continued and the diet also remained the same, the percentage rose again to 2. The patient was a good deal worried by changing houses and other causes, to which, as well as to irregularities of diet, the relapse was doubtless due. Uranium was continued, the amount of sugar fell again, but did not entirely disappear. In February the patient was seized with a very severe attack of influenza and was exceedingly ill. The uranium was stopped for the time, and, as I afterwards learnt, was not subsequently resumed. The influenza caused a great relapse in the diabetes, the amount of urine increasing largely and the percentage of sugar rising over 3. As the patient recovered from the influenza the percentage fell, the amount of urine, however, still remaining large. When seen six months after the influenza the patient looked feeble and ill, though very much better than she had been; the percentage of sugar was between 2 and 3, and the quantity of urine about 1600 to 1800 c.c. daily—that is to say, she was about in the condition in which she was when first seen by me. It is proposed to administer uranium again by-and-by. The third case is that of a patient who was in the hospital, treated in the usual way for diabetes and with various drugs, but chiefly with codeia. She had reached a condition of equilibrium and was passing about 7 per cent. of sugar, an amount which had been fairly constant for many weeks. She was then placed upon uranium nitrate, at first five grains and later ten grains three times a day. The small dose produced no effect, the large dose showed its effect rapidly in the reduction of the amount of urine, on the average from six pints to four; and when the drug was still further increased to fifteen and twenty grains the percentage also fell, and on leaving the hospital it was only 4. The administration of uranium, therefore, seems to produce striking results in diabetes. It causes first a reduction in the amount of urine and subsequently a great fall in the percentage of sugar. As the patients were under constant conditions in respect of diet and general regime it is fair to refer all these results to the action of the uranium, for the administration of the uranium caused the quantity of the urine and the percentage of sugar to fall. On withholding the uranium both increased; on giving it again both once more fell, until in the one case the sugar entirely disappeared from the urine, and in the other almost entirely. Although uranium does not cure diabetes it seems to have a power of controlling the secretion of sugar greater than is possessed by any other drug Dr. West was acquainted with. It is suggested that its action may be due to its power of checking amylolytic digestion and that it may be most useful as an adjuvant in those cases of diabetes in which diet largely influences the amount of sugar, so as in such a case to lead even to the complete disappearance of sugar from the urine.

THURSDAY, AUG. 1ST.

Acute Lobar or Croupous Pneumonia: its Etiology, Pathology, and Treatment.

A discussion on this subject was introduced by Dr. R. DOUGLAS POWELL. Great interest, he said, was manifested in this important subject, and the large lecture theatre of the Conjoint Examination Hall was full to overflowing when Dr. Powell rose to introduce the discussion. He commenced by regretting that he could not record any practical abatement of the mortality from pneumonia, nothwithstanding improved public health with regard to most other diseases, and especially those of the zymotic class, including tuberculosis; and, moreover, that one-third of those attacked were in the zenith of vigour and work. He pointed out that the prevalence of pneumonia, whilst having no direct relationship to severity of climate as dependent upon latitude, was nevertheless directly influenced by seasonal lowness and by changeableness of temperature in temperate climates. Individual imprudence was a factor which could not be statistically estimated, yet which told importantly in places where climatic changes were considerable, and in localities where the vicissitudes of social life, and where manufacturing and office industries involved frequent exposure to sudden changes of temperature. Probably one-third of the cases of pneumonia were attributable to chills thus contracted through hygienic imprudence, especially amongst those past middle life; and the fatalistic and inadequate view that the reception of a microbe was alone sufficient to cause pneumonia encouraged such imprudence. When the temperature ranged above 104°F., however, it approached hyperpyrexia and became an important source of nervous exhaustion and cardiac failure. The ice cradle, cold pack, cold bath, and cold sluicing were valuable, aided by quinine or salicine. The pathology of chill, with regard to the exact temperature, vaso-motory, and other phenomena which attended it, and their relationship to the variability and multiplication of various microbic organisms, would form an admirable subject for experimental inquiry. The normal compensatory powers of the human organism with regard to temperature might be surprised and defeated by sudden exposure under conditions of temporary depression or debility. Pneumonia tended to complicate fevers rather in their apyrexial stages, and it was at the lower ranges of human temperature that microbic cultivation was most vigorous. There were other conditions besides chill predisposing to pneumonia, such as depressed vitality, privation, the uræmic state, rheumatic conditions, diabetes, &c.; but he (Dr. Powell) would pass to that which was the most important factor for discussion in its etiology—viz., how far was the reception and cultivation of a specific organism essential? Friedlander's, Fraenkel's, and Klein's microbes were all candidates for the honour of disseminating pneumonia amongst us, Fraenkel's pneumococcus being most in favour. Undoubtedly pneumonia was a specific general (and therefore a microbic) disease, but the pneumococcus of Fraenkel presented some difficulties which had to be cleared up before it could be finally accepted as *the* germ of pneumonia. Besides its prevalence (80 per cent.) in pneumonia it was held to account for a large proportion of many other diseases—purulent meningitis, ulcerative endocarditis, otitis media, &c. — diseases which had little pathological resemblance to pneumonia and with which pneumonia was not commonly associated. In secondary inoculations septicæmia was the most common result, and was too loosely accepted as valid evidence of specific virulence. In the cases of pneumonia published by Osler of Montreal ulcerative endocarditis occurred as a frequent complication. Dr. Powell could not understand this, as he had never seen the disease a direct sequel of pneumonia. The presence of the coccus in healthy

Digitized by Google

secretions was a fact which, however, did not militate against its possible virulence under conditions favourable to its aggressive cultivation. Pneumonia resembled such diseases as tuberculosis, erysipelas, acute rheumatic tonsillitis, and influenza, which, although possessing a specific organism, required for their efficient etiology certain additional conditions of impaired vitality, local or general, to enable the organism to become aggressive, and it was by ascertaining and avoiding these conditions that much would be done to prevent and combat the disease. Instances might be adduced in which pneumonia had appeared to spread by direct infection. Such cases were rare, however, and if the more important causes which lead to spread through a household (e.g., sewer-gas emanations, epidemic influences, and influenza) were allowed for, but few cases were left to be accounted for by contagion. Dr. Powell hoped the question of infection would be fully discussed. He had heard of striking instances of infection, but had no personal knowledge of it. Pythogenic differed from croupous pneumonia in the smallness of the areas of lung involved and their more scattered distribution and greater liability to metastatic change in the fluctuating temperature and frequent termination by lysis. The microbic organism was the same, but was associated with another microbic poison of a septic kind. As the pneumonia advanced leucocytosis occurred. White cells increased to a great extent in the pyrexial condition. When the temperature fell the percentage of white cells diminished, but became more abundant if any fresh rise of temperature took place. Dr. Powell defended the present routine treatment of pneumonia as sufficient and useful for ordinary cases—namely, attention to the conditions of the skin and excreta, a strict dietary, and absolute rest, which relieved the burden imposed on the right side of the heart. But there were certain symptoms of danger in more severe cases which required a more active and farseeing treatment, and chief amongst these was hyperpyrexia. The pyrexia of pneumonia was brief, normal to the disease, and unfavourable to microbic activity, and, therefore, its treatment by antipyretics was harmful. The development of the germ was checked by a high temperature. In most of the favourable cases—i.e., in normal pneumonia—this generally rose to 104°, and at this temperature the growth of the germ was checked. It was not advisable immediately to reduce the temperature below 102° on this account. In Dr. Powell's opinion the reduction of temperature by drugs that are not distinctly inimical to micro-organisms was distinctly harmful; and if the temperature was brought as low as 99°, an overdose of the drug had been given and the patient would suffer. These drugs were far better than antimony and aconite, both of which produced profound cardiac depression. In the pneumonia of drunkards tincture of iron in large doses could with profit be added to the medicine. Pain, which might be due to two causes—distension of the lung or pleurisy—required special treatment. The pain of distension might be met by ice compresses, but was better treated by leeches and hot poultices; that of pleurisy by a blister with superposition of hot poultices in quick succession. The cause of the pain having been thus attacked it might be soothed by a moderate dose of morphia. Ice compresses both profit and suffer by their too enthusiastic advocacy. Children and young adults were, he thought, the most suitable subjects for this treatment. Active delirium or sleeplessness suggested—(1) cumulative doses of food and stimulants, followed by (2) a sufficient doses of morphia and strophine, with (3) oxygen inhalation in case of cyanosis and sweating. Dr. Powell recommended in grave cases a more timely use of oxygen. It was a powerful heart tonic, and he considered its use was often postponed until too late. It also had a marked effect in diminishing restlessness, and when the patient is sleeping if a little were from time to time administered it often enabled him to remain asleep. Cardiac failure was brought about by impaired pneumogastric innervation, by impaired nutrition of heart muscle by defective blood, and by over-distension of right cavities and depletion of left cavities. Strychnine or caffein, sometimes with digitalis, subcutaneously, maintained nerve power; oxygen in occasional doses nutrified heart muscle; and venesection or leeching, with depletion of portal system, in combination with the other remedies, relieved the congested right heart in threatening cases. Against the danger of excessive extension of exudation he believed the timely substitution about the fifth day of acid remedies or tonics, sometimes including iron and digitalis, were the best remedies. He doubted the value of ice applications in this regard. He could not as yet find much reliable experience to sanction the antitoxic treatment of pneumonia, and until our knowledge was more precise with regard to the microbe of pneumonia and its toxine, and until further researches on the lines which were already at work had been completed and compared, antitoxic treatment, fraught with its own dangers, would be premature in the human subject.

Dr. WASHBOURN considered acute lobar pneumonia to be a specific disease. In broncho-pneumonia the inflammation spreads by the bronchial tubes. In lobar pneumonia it spreads directly through the alveoli. He admitted that a few cases occurred without the specific germ being present, but pointed out that in throat inflammations many different germs produced inflammation. In post-mortem examinations he had never failed to discover the germ if he examined portions of lung that had recently been attacked. It was easier to detect the germ in lung tissue than in sputum. If the products from the germ cultivations were injected into animals they often died from septicæmia. He considered the crisis due to the formation of a substance improperly called an antitoxin.

Dr. AULD (Glasgow) agreed that pneumonia was a specific disease.

Dr. DRESCHFELD (Manchester) confined his remarks to influenza pneumonia, which he considered highly infectious. He thought the sputum should always be disinfected.

Dr. J. E. POLLOCK considered the question from a clinical point of view. He admitted that in almost all cases a germ was present; but was it always the cause? He quoted the case of a clergyman whom he had recently seen in consultation in the country. The gentleman was in perfect health and drove out in an easterly wind. On returning home he was immediately seized with a chill. The next day on examination consolidation was present, and in a few days he was dead. Was it to be assumed, Dr. Pollock asked, that in such a short time the development of micro-organism could be the cause of such rapid changes of structure. It was impossible, he said, to take laboratory knowledge alone. All theoretical knowledge must be brought down to clinical experience.

Dr. CLIFFORD ALLBUTT enlarged on the great advantages that could often be obtained from oxygen inhalation.

Dr. GIBSON to some extent opposed the views expressed by Dr. Pollock. He pointed out that in India cholera had existed for 200 years, and clinical observation did not even suggest its cause, but the bacteriologist showed it to be due to the presence of a micro-organism.

Dr. COGHILL spoke from personal experience of the benefit to be derived from aconite. He said that in his own case it gave very great relief to the most distressing symptoms.

Dr. D. B. LEES spoke at some length on the benefit to be derived from ice, but he considered the treatment must be pushed to its full extent. The greatest benefit was to be obtained in children and young adults.

Dr. POPE considered that the pneumonia complicating typhoid fever was particularly infectious.

Dr. SHINGLETON SMITH (Clifton) raised the question of the treatment by large doses of digitalis. He particularly commented on the statistics of Dr. Petresco of Bucharest, who had published 1300 cases with a mortality of only 2 per cent. These had been treated by four to eight grammes daily of powdered digitalis; he could not doubt, but could hardly understand these results. When compared with the results of English hospital treatment, which showed a mortality of 20 to 25 per cent., they were very striking. He merely regretted that Dr. Petresco, who had been present at the commencement of the discussion, was not there to explain.

Dr. SQUIRE objected strongly to the word croupous and advocated the term lobar pneumonia.

Dr. DOUGLAS POWELL, in reply, regretted that Dr. Washbourn had not more time to explain his views on the antitoxin treatment of the disease. He thought that Dr. Foxwell and Dr. Clifford Allbutt had rather mistaken his views as to the advantages of oxygen. He did not doubt its efficacy and advocated its earlier use as a cardiac stimulant. He agreed with Dr. Lees as to the use of ice in young patients; certainly in children he would rather use ice than a blister.

SURGERY.

THURSDAY, AUG. 1ST.

The Pathology and Clinical History of some Rare Forms of Bony Ankylosis.

Mr. HOWARD MARSH read a paper on this subject. Two

Digitized by Google

propositions used to be laid down about bony ankylosis, he said; the first was that it was the only way in which a joint could recover after suppuration, and the second was that it was always due to suppuration. Neither of these statements can now be upheld. Suppuration is not necessarily followed by bony ankylosis, as, for instance, in pyæmia and in some forms of tuberculous disease; in fact, we may say that bony ankylosis is a rare ending to suppuration in a joint. Also, bony ankylosis may occur without suppuration. It is usually said that there are three ways in which tuberculous disease of a joint may end—viz., perfect recovery, fibrous ankylosis, or bony ankylosis; to these must be added a fourth, in which tuberculous disease occurs in a joint, and the inflammation is not active, the signs are but slightly marked, and yet the condition ends in ankylosis. Several cases were cited, and in one of these, in which the elbow was affected, excision was performed, the excised portion of bone being shown. A similar process can probably also occur in the vertebral column. Charcot's disease also may possibly end in ankylosis apart from any suppuration. Charcot himself has described a case in which ankylosis occurred in a tabetic foot. Three specimens were shown from the Cambridge Museum with ankylosis of some of the bones of the foot; there was no history accompanying them, but as the joint surfaces were unaltered and the ankylosis was due to ossification of ligaments, they were probably not cases of suppuration, but very possibly they were tabetic. Further evidence that ankylosis might be nervous in origin was found in a case where bony union occurred in an inter-phalangeal joint after injury of the median nerve in the forearm. Other instances of ankylosis without suppuration were to be found in gout, as shown by a specimen of the bones of a hand, in gonorrhœal rheumatism, and also in lateral curvature of the spine; this latter is decidedly common. A case of multiple bony ankylosis was described; it occurred after an attack of what was apparently rheumatic fever; all the joints of the lower limb became stiff, and at the patient's death it was found that the union was bony. In the spinal column in osteo-arthritis bony ankylosis is common, but it is to be noted that the fixation is really due to ossification of the ligaments surrounding the joints, without any interference with the joint surfaces themselves. Ankylosis may be reparative, as in pyæmia or tubercle, or it may be degenerative, as in tabes. As to treatment, four propositions may be laid down: 1. When bony ankylosis is likely put the joint in good position. 2. We possess no means of preventing it. 3. Passive movements, far from retarding bony union, seem even to favour it. 4. After it has occurred excision or osteotomy may be useful.

Mr. TARGETT said that the specimens showed well the difference between true bony ankylosis of a joint and ankylosis caused by ossification of the ligaments surrounding the joint (this latter being comparable to myositis ossificans). The most rapid forms of bony ankylosis were the result of pyæmia.

Mr. BOWLBY mentioned that in the case already referred to of injury to the median nerve most of the joints in the hand were ankylosed. He thought that joint changes were by no means rare in nervous diseases, and considered it probable that in the future it would be shown that osteo-arthritis was due to some nervous lesion.

Mr. BLAND SUTTON mentioned that it was not rare to find an ankylosed occipital and atlas, yet the cause was undetermined. Mr. Arbuthnot Lane had attributed them to pressure on the head, and so thought they occurred in costermongers. A similar condition he had found in the museum of the Veterinary College at Paris in the bones of oxen, and in this case it was probably due to their drawing loads by means of yokes fastened to their horns. Ankylosis by ossification of the ligaments of the spine was common in horses.

Mr. T. S. ELLIS (Gloucester) said that three names—hallux valgus, hallux rigidus, and hallux dolorosus—were applied to one and the same condition—viz., ossification of the metatarso-phalangeal joint of the great toe. If the great toe goes outwards above the other toes there is very much less pain than if it goes outwards below the other toes.

Mr. MARSH, in reply, said that the fact that many cases of ankylosis of the spine occurred in old people was no proof that they were not tuberculous; he had seen a case of angular curvature at the age of sixty-nine.

A Hitherto Undescribed Locality in the Male Urinary Bladder where a Stone may elude Contact with the Sound.

Mr. BUCKSTON BROWNE read a paper on the above subject. He said there were three well-known forms of vesicle pouch where a urinary calculus might lie and escape detection by any instrument introduced by the urethra; the first was the ordinary sacculus, the second a post-trigonal pouch, and the third a post-prostatic pouch. He had recently met with a fourth form, viz., a pouch situated between the enlarged lateral lobe of the prostate and the bladder wall. In his case the stone lay in such a pouch on the right side. Supra-pubic cystotomy was the only satisfactory method of dealing with such a case. Sometimes by dilating the bladder, and keeping an elastic ligature round the penis, it may be reached by the urethra.

Mr. MAYO ROBSON (Leeds) mentioned that he had had a case where a stone had lodged in a pouch between an enlarged prostate and the anterior wall of the bladder. Also in a case of supra-pubic prostatectomy he had found three calculi in a post-prostatic pouch.

Necrosis of Femur.

Mr. NEWMAN (Stamford) showed a specimen of necrosis of the left femur removed by amputation through the thigh in a patient who had been under his care for many years. Symmetrical necrosis had occurred of the popliteal surface of both femora, and portions of necrosed bone were removed. Recovery occurred, but after intervals of health other operations had to be performed, and ultimately amputation of the left thigh had to be done. Recovery followed. The specimen showed how very thin was the shell of bone which had supported the patient's weight for so many years.

The Surgical Treatment of Cysts, Tumours, and Carcinoma of the Thyroid Gland and Accessory Thyroids.

Mr. H. TRENTHAM BUTLIN opened a discussion on the Surgical Treatment of Cysts, Tumours and Carcinoma of the Thyroid Gland and Accessory Thyroids. He commenced by saying that of tumours of accessory thyroids he knew nothing; he had seen cases where tumours had occurred apparently separately from the thyroid gland, but on operation they had always been found to be connected with the gland. Of another portion of the subject also he could say nothing from personal experience, and that was with regard to the surgical treatment of malignant disease of the thyroid gland; he had never seen a case in which removal was possible; at a very early stage infiltration of the surrounding structures occurred, and this is equally true of carcinoma and of sarcoma. Malignant disease of the thyroid gland may occur at an early age; he had seen it as early as fifteen years in a boy. It is of course quite possible that malignant disease of the thyroid gland may be met with at a stage early enough for successful operation, but it must be very rare. As to cysts and adenomata, much progress has been made within the last few years, and now we know that most cases of partial enlargement of the thyroid gland are not true enlargements of the gland itself, but are due to the presence of separate cysts or adenomata in the substance of the gland, from which they are easily separable, as they are fully encapsuled. The operation performed now is very much simpler than formerly, as it is recognised that it is a separate tumour, and that therefore no part of the true substance of the thyroid gland need be removed. All that was needed was a simple incision down to the capsule, which was opened and the tumour shelled out; any bleeding vessels were tied, and a drainage-tube was introduced for the first few hours. The operation was best described by the name "enucleation." There are few complications of importance which may occur during the operation. One of these is hæmorrhage. In the out-patient room he saw a woman aged forty who had a cyst of the thyroid gland; he punctured it and fluid came out, at first clear, but rapidly containing more and more blood; a large quantity of blood was thus lost, and as the hæmorrhage showed no signs of ceasing a pad was put on; this completely checked the bleeding, but a few days later the patient returned and said that whenever the dressing was shifted bleeding occurred. She was admitted into the hospital and the cyst laid open; the hæmorrhage was now profuse, and the sac had to be plugged from the bottom. The patient completely recovered. Hæmorrhagic cysts are characterised by containing soft, vascular, intra-cystic growths. The chief objection to the operation of enucleation is the scar. It is always unsightly and may be very conspicuous, and so in young people it was desirable to avoid it if possible. The alternative operation is injection. The directions laid down by Sir Morell Mackenzie when he introduced this method of treatment should be carefully followed. He has used the method with success in many cases, and the

Digitized by Google

scar left is almost indistinguishable. Failure may occur, or even death may follow (probably from thrombosis and embolism); paralysis of the vocal cords or diffuse suppuration; but all these results are probably due to the selection of unsuitable cases. Nothing can be more satisfactory than the injection of a cyst, and nothing can be worse than injection of the parenchyma of the gland. The cases to select for injection were cysts of moderate size with no intra-cystic growths, and occurring in young patients in good health. If the cyst is old and thick-walled it is not suitable for injection. A small amount of intra-cystic growth is probably no real hindrance to injection. The cannula on being introduced shows, by the escape of fluid, that a cyst has been punctured and not thyroid substance, so the injection of gland tissue need never occur. After failure by injection excision may be done.

Dr. W. W. KEEN (Philadelphia) said that the question of anæsthesia was important. He had recently had the opportunity of seeing a number of cases operated on in Continental Europe, and there he found that anæsthetics were hardly used at all for this operation; occasionally an anæsthetic was employed while the skin incision was being made, but then given up. Kocher said that the hæmorrhage was so very much less as the respiration was much less embarassed. Another surgeon when about to tie the thyroid artery talked to the patient to make him speak, in order to be sure that the recurrent laryngeal nerve was not being injured by the ligature. He had noticed also that the skin incision was transverse with slight convexity downwards; by this the scar is very much less noticeable. Another method of rendering the scar invisible was that introduced by Halstead of Johns Hopkins University—namely, subcutaneous suture by silver wire, which is made to pass from one face to the other of the wound without perforating the epithelium at all; another point in favour of this method was that septic micro-organisms in the skin are not disturbed. Hæmorrhage during the operation was often troublesome, and he had noticed how very careful Swiss surgeons were to arrest the whole of the hæmorrhage, even if not proceeding from a visible vessel. In cases of extirpation all the veins and arteries are systematically tied.

Mr. CHARTERS SYMONDS said that he had had forty-four cases of removal of portions of the thyroid gland without any harmful result; of these, twenty-nine were for adenomata and cysts. As to carcinoma, on one occasion severe dyspnœa had occurred, and in order to perform tracheotomy he had had to cut right through the new growth in order to reach the trachea. Practically no hæmorrhage occurred, and it was easy to open the trachea with the finger. For the enucleation of cysts he prefers a median vertical incision, as giving a better view of the whole of the tumour. Hæmorrhagic cysts contain intra-cystic growth. If the cyst when exposed is white or bluish no hæmorrhage will occur, but if it be purple hæmorrhage is very likely to result. Sometimes the wall is very thin and cannot be dissected out. In these cases, if the whole tumour be brought outside the wound the hæmorrhage ceases. With regard to anæsthetics, ether was used in two of his cases, and there was much hæmorrhage. Substernal cysts are very troublesome. He agreed with Mr. Butlin as to the value of injection in suitable cases, but acknowledged that it was by no means easy to determine which cases were suitable. The length of scar may sometimes be diminished by emptying the cyst before enucleating it; by this means a large cyst may be removed through an incision not much more than an inch long.

Mr. MAYO ROBSON (Leeds) thought that malignant disease of the thyroid gland must be very rarely suitable for operation. In one case of dyspnœa due to malignant disease of the gland he had employed intubation with success. In some cases of cyst the cystic formation seemed to be diffuse, so that it was impossible to remove the cysts individually, and it was necessary to remove half a lobe. With regard to anæsthetics, ether is bad, and he prefers in many cases to use no anæsthetic except for the skin incision. Tracheotomy may be needed during the operation for marked cyanosis.

Mr. JAMES BERRY remarked that though he had seen twenty cases of malignant disease of the thyroid gland he had never seen one which could be operated on. In the majority of cases of cysts and adenomata no operation is required and he considers that some very definite reason for operation should be present before any surgical treatment is undertaken; the symptom of most importance is dyspnœa. Of 36 cases in which he had operated, 31 were operated on for dyspnœa, 1 for dysphagia, 1 for an old suppurating sinus, and only 3 for deformity. Two classes of operations may be required, extirpation and enucleation. Enucleation is only advisable for a single well-defined tumour on one side only; but if many adenomata or cysts are present extirpation must be performed. The more nearly globular a tumour is, and the smoother its surface, the more likely it can be removed by enucleation. The most serious tumours are those situated low down behind the sternum. A cast was shown of a case where urgent dyspnœa was present, from pressure on the trachea of a thyroid tumour beneath the sternum, yet practically no swelling was visible in the neck.

Mr. C. B. KEETLEY said that he considered that early malignant disease was suitable for operation, as it was encapsuled for some time, but the difficulty was its early diagnosis. He had operated on three cases of enlarged thyroid without an anæsthetic, except for the first incision, and the operation was very well borne. He did not consider that drainage was required in any case.

Mr. A. E. BARKER had had two cases of malignant disease of the thyroid gland, in which he had operated. One was on account of a very large tumour which needed a skin incision of fourteen inches. Glands were involved, being traced down to as far as the apex of the pleura, and were removed; two years later another diseased gland was removed, and now—six years later—the patient was quite well. In the second case the whole of one scalenus anticus was affected with the growth and was removed with the tumour; the patient completely recovered, and no recurrence occurred.

Mr. JORDAN LLOYD (Birmingham) had met with two cases where enucleation was impossible, the tumours consisting of cysts and solid matter. He had also had two cases of very severe hæmorrhage. He did not consider the scar objection to be of much importance.

Mr. THELWALL THOMAS (Liverpool) had met with two cases of tumours occurring in accessory thyroid glands. With regard to the scar, he thought more attention should be paid to what have been called the "lines of cleavage" of the skin; an incision made along such a line always resulted in a smaller scar than one made across a line of cleavage; this, he considered, accounted for the increasing width of vertical scars in the neck.

Mr. R. C. CHICKEN (Nottingham) said that for cysts he never used any other method than enucleation. Isthmoidectomy he considered of value for cases of serious unilateral enlargements of the thyroid gland.

Mr. CATHCART thought that there were gradations in malignancy, and that this fact accounted for the different results of operation in malignant disease of the thyroid gland.

Mr. BUTLIN, in reply, said that a great objection to the transverse incision was the appearance of the scar, which was very suggestive of cut-throat. In an ordinary case the amount of blood lost during an enucleation was very small. He did not approve of puncturing a cyst before removing it, even to save some scar, as the operation of enucleation was much more difficult.

OBSTETRIC MEDICINE AND GYNÆCOLOGY.

THURSDAY, AUG. 1ST.

The Early Diagnosis of Malignant Disease of the Uterus, and the Treatment by Partial or Total Excision.

Mr. J. KNOWSLEY THORNTON, Consulting Surgeon to the Samaritan Free Hospital, opened a discussion upon this subject. The speaker stated that he considered it to be his duty to give his own practical experience and the views founded upon it, and not to attempt a *résumé* of the work of others, but merely to give a lead to the expression of their experience, he appealed strongly to the general practitioners to take more note of the trivial departures from healthy normal menstruation, and insisted on a demand for early internal examination. He pointed out that it is in their hands and not in those of the consultants that advance in early diagnosis lies, and he appealed to them when they are only suspicious to lose no time in getting their suspicions confirmed or dispelled by consultation with someone of greater special experience than themselves. In answer to the question, What is cancer? he briefly described some of its most reliable symptoms and discussed the propriety of removing small

Digitized by Google

portions for microscopical examination. He then classified the various forms of malignant disease which attack the uterus, and passed on to the method of treatment suitable for each variety. He advocated supra-vaginal amputation of the cervix for adenoma and epithelial cancer of the vaginal portion, and pointed out that to remove the uterine body is useless in most of these cases. He then described the operations of supra-vaginal amputation of the cervix and vaginal extirpation or hysterectomy. He discussed Williams's view that a fresh outbreak after years is not a recurrence but a new appearance of disease in a patient liable to develop it, and pointed out the importance of this theory on the extent of operation advisable. He concluded with a brief discussion of the points that should guide in the selection of cases as suitable for one or other of these operations, deprecating operation in hopeless cases, and insisting that the sound rule of surgery, only to operate for malignant disease when it can be efficiently and entirely removed, should be rigidly applied.

Professor MARTIN (Berlin) did not think that symptoms alone (such as pain, altered secretion, or even bleeding at the climacteric) could settle the diagnosis in a doubtful case. In Germany microscopic examination alone was relied on, but it required extreme experience and education in the microscopic anatomy of the uterus to say what was really malignant. If the diagnosis was not plain he would let the case alone. He had been struck on a visit to Italy last year by the fact that when the uterus was removed even in the most suitable cases there had been recurrence, so that in that country the question of operating at all in cancer was at present *sub judice*. He objected to the supra-vaginal operation, because in his hands all the cases so done had recurred. Further, adenoma of the cervix was rare, while nearly all cancer cases were epithelial. In cancer of the breast the surgeon removed not a part, but the whole of that organ; the same practice should apply to the uterus. If the disease had also appeared in the vagina he would remove it if possible and then the diseased uterus; but if the lateral ligaments were involved he would do no radical operation. As to the complete vaginal hysterectomy, the results in Germany of the immediate operation were assured. The mortality was only from 4 to 10 per cent. He recommended the use of the hot cautery to destroy any slough before doing the radical operation. They had recently in Germany had cases in which they had performed the abdominal operation and removed affected glands as high as the bifurcation of the aorta.

Dr. POZZI (Paris) said if cancer was diagnosed either in the breast or uterus the proper line of procedure was to remove the whole organ. The reason why the total extirpation of the uterus was not done formerly so much was because the early results were bad. Now the *technique* was improved, the results were better, and the same line of surgical treatment should be applied both to the uterus and to the breast. The supra-vaginal operation was, in his opinion, a difficult one, it was a long one and tiresome to the operator, and was often attended with hæmorrhage. If done before the menopause it might be attended with atresia of the cervix and distension of the tubes. He had seen three cases of hæmaturia and hæmato-salpinx follow the supra-vaginal amputation, in each of which he had to perform an abdominal operation for their removal. The great point was to operate early. The method might vary; and, for himself, he was using forceps now more than formerly. With forceps he had often performed the operation in less than ten minutes. His advice was to operate when the disease was limited exactly to the uterus or upper part of the vagina. If the disease had extended to the lateral ligaments he would not do the radical operation. He would formulate his rules for operating in this way: when the uterus was mobile—in other words, when it could be easily pulled down—the operation was an easy one for the surgeon and a good one for the patient. On the other hand, if the organ could not be pulled down it was both a difficult and a bad operation. In cases in which the total extirpation could not be done he would curette and cauterise with the old hot iron of Baker Brown, not the Paquelin (which acted too superficially). This plan prolonged life and could be repeated if required. He believed, no matter what operation was done, there was recurrence in three, four, or five years. He never saw a case lasting longer than three years without recurrence, but in the interval the patient had health and comfort. In a word his views were: operate by total extirpation in the early cases, and in the advanced curette and burn.

Dr. LUSK (New York) was bound to say his experience was that when the disease was in the cervix, even after total extirpation, it recurred rapidly. He was inclined to go back to the high partial operation. In the advanced cases he liked the plan of scraping out the disease and then packing the cavity with chloride of zinc solution (four to six drachms to the ounce). After the slough came away there was a clean granulating cavity, even in cases usually rejected.

Dr. SCHARLIEB emphasised the great importance of impressing on women the mistake of neglecting suspicious symptoms—as, for example, hæmorrhage occurring at the menopause. Women must be taught not to regard this as a normal phenomenon, as they too often did. Further, they as medical practitioners must all pay far more attention to early diagnosis, and students should be better educated practically in this direction in the methods of examination.

Professor MURDOCH CAMERON (Glasgow) said his experience was that many women thought they had cancer who really, on examination, were found not to have this disease, while those who came with malignant disease were, in the vast majority of cases, too late for operation.

Professor JAPP SINCLAIR (Manchester) said the diagnosis was more difficult in cases before than after the menopause. In lacerations of the cervix certain changes sometimes took place, and in such circumstances the diagnosis was very difficult. He mentioned a test he had found very useful in the diagnosis of cancer. If the operator used a sharp spoon in the early stage of epithelioma of the cervix he could scrape away the tissue, as it was friable, and a cavity was left. In a non-malignant case—say, hypertrophy—an excavation will not be caused; there may be bleeding, but no friable tissue will come away. The supra-vaginal operation was not justifiable before the menopause, as it did not cut off the blood supply and did not bring about quiescence in the pelvis. The total operation was simpler than the supra-vaginal amputation. He had himself a run of thirty cases with no death, and indeed with no anxiety. He preferred the ligature, as he thought less blood was lost in this way. He sutured the peritoneal flaps and put an indiarubber drainage-tube at one side. He thought the drawback of not suturing the peritoneum was that pressure caused sloughing, and there had been cases of vesico-vaginal fistulæ and obstruction of the bowels.

Dr. PLAYFAIR said Mr. Thornton had advised the most reaching surgical method when the disease could be diagnosed. In his (Dr. Playfair's) opinion the partial operation was not the most reaching plan. He regarded the partial method as an unsurgical operation. He said if in a case of cancer of the breast the surgeon removed the whole organ, why in malignant disease of the uterus should the gynæcologist be told to do a partial excision of that organ? It was strange that England was the only place where the partial method of operation is still performed by some. He thought this was due to the fact that in former times total vaginal hysterectomy was attended with a high mortality, but now that the death-rate had fallen to 5 per cent. this argument could no longer apply. While microscopic examination was of value when the disease was advanced, he was suspicious of its utility in the early stage.

Mr. J. W. TAYLOR (Birmingham) thought more time must be devoted to the pathology of the uterus before they could rely on microscopic examination. He had two cases which the microscopists said were malignant, but the subsequent history was against this view. He thought a good rule to follow was to regard any case with suspicion in which examination caused bleeding. Total vaginal extirpation he regarded as the best operation.

Dr. CAMPBELL (Belfast) also advocated the total removal of the organ in uterine cancer.

Mr. BOWREMAN JESSETT could not regard the microscope as reliable. The supra-vaginal amputation was not always an easy operation, it was sometimes attended with bleeding. He had 4 per cent. mortality, which was half that of total excision. He used ligatures.

Dr. W. DUNCAN pointed out the importance before operating of making a rectal examination to see whether the utero-sacral ligaments were infiltrated or not, as they might be when bimanual examination conveyed the sensation that the uterus was quite mobile. No operation should be done if these ligaments were infiltrated. At the Obstetrical Society some years ago (1885) he had advocated in a paper the partial operation, but he had since then, owing to the

Digitized by Google

improved technique, changed his views, and he now advised total extirpation, which had been shown to have a mortality of from 4 to 10 per cent. He thought ligatures safer than forceps.

Dr. SMYLY said those who had attended Professor Martin's Clinique in Berlin knew that the microscopic examination was done in a most thorough way at the same time and conjointly by his assistant, who had a special training and knowledge of the microscopic pathology of the uterus. He (Dr. Smyly) advocated the total operation, which he performed. The question of special importance now was whether cancer was inoculable or not. He thought, acting on the theory that it might be inoculable, the wise course was to use the cautery before removing the uterus. In this way the cut tissues were protected from contact with the cancer structures.

Dr. DONALD (Manchester) spoke of the value of the test mentioned by Dr. Japp Sinclair, and advocated total extirpation of the uterus in cancer. He used chromic gut, which he cut short.

Dr. H. R. SPENCER agreed with Mr. Thornton that the supra-vaginal operation was the better one. It was without danger in skilled hands, and they must remember that when recurrence took place in such cases it was in the broad ligaments. He thought the operator should be his own pathologist.

Dr. A. J. SMITH (Dublin) said in his opinion an objection to the partial operation was that in cases in which total excision had been done, the disease being supposed to be limited to the cervix, when the uterus was examined after removal in some of the cases malignant disease was found in its body. To his mind, the great difficulty was in the diagnosis of adenoma and hyperplastic endometritis from cancer, especially if there was a diffuse uniform intra-uterine swelling. He thought the use of the microscope of great value in the diagnosis. If after dilatation of the uterus he found a circumscribed outgrowth he removed a portion and had it carefully examined by a microscopist, and if he pronounced it malignant he removed the organ. The cases in which the growth in the interior of the uterus was diffuse required very careful watching. He advocated total excision, and he used the cautery, as he believed in local inoculation.

Dr. AMAND ROUTH spoke of the value in diagnosis of the impression conveyed to the finger. At the Samaritan Hospital they had only about seven or eight cases in the year that they could operate on radically.

Dr. MORE MADDEN, Dr. HAYES, and Dr. HEYWOOD SMITH also spoke in the discussion.

Mr. KNOWSLEY THORNTON, in his reply, said the discussion had confirmed him in his opinion of relying less on the microscope and more on the clinical diagnosis. As to the question of partial and total extirpation, they must remember that the disease spreads from the cervix into the broad ligaments and not into the body of the uterus. He denied the analogy between the heart and the uterus. His own personal experience (and in this discussion it was that which he gave) was that in supra-vaginal amputation he had no deaths, and in the after-life history he got the best results. As to the question of removing the tubes, in two cases of cancer of the body of the uterus which he had removed he left the tubes and the patients are still well. He would not, as a rule, remove the ovaries. As to the technique of the supra-vaginal amputation, he thought the special point was the securing of the uterine arteries, after which the risks and difficulties were much less. As to the after-life history he was suspicious that sooner or later patients too often died with a recurrence of the disease in some part of the body. His objection to forceps was the risk of sepsis from sloughing of tissue grasped in their blades, and in their removal there was the risk of breaking up tissue, which decomposed and gave rise to septic absorption.

PUBLIC MEDICINE.

THURSDAY, AUG. 1ST.

Hospital Isolation, House Quarantine, and Disinfection.

A discussion on this subject was opened by Dr. PHILIP BOOBBYER, medical officer of health of Nottingham. What is chiefly required, he thought, at the present time is more uniformity of action and aim on the part of public authorities with respect to all matters affecting the isolation and disinfection of the infectious, sick, and convalescent. Large and expensive hospitals are now provided, or in course of being provided, in most inhabited districts, but all that relates to their administration is in many cases practically left to the discretion of two or three persons, who have nothing more reliable to guide them than their own often original and independent notions of what they should do. Single hospitals have in some instances been built to meet the requirements of very wide surrounding areas. It will often be a matter of difficulty, as Dr. Thorne and others have pointed out, to secure the removal of patients from their distant homes to the central hospital; but this difficulty will be increased to an insuperable degree if—as we hear in many quarters to be the case—a charge is to be made for admission. There is still much to be said in favour of local hospitals for the more isolated inhabited spots in large districts—say, for such as are over twelve miles from the central hospital. These small hospitals should be permanent structures, but could be closed when not in use, and opened at short notice when required, with the nucleus of a staff drafted from the centre, where a permanent establishment should be maintained. There can be no doubt that a reliable and authoritative memorandum advising authorities upon all points in connexion with isolation and disinfection is much needed. Plenty of excellent data exist, but they require to be codified in order to render them accessible and intelligible to those who have little opportunity of finding and digesting them in their present scattered and fragmentary condition. More uniformity is required in the lists of diseases for which isolation is professedly practised in various parts of the country. The time has probably come when public authorities might, with advantage, be advised respecting the nature and degree of benefit to be expected as a result of isolation, disinfection, and other kindred precautions in the case of particular diseases. A revision is certainly necessary of much that has hitherto been taught respecting the criteria for estimating the continuance or decline of infection, and the actual seat, or at any rate the principal seat or seats, of infection, in all stages of certain diseases, as, for example, small-pox and scarlet fever. Small-pox was on one occasion found by Dr. Boobbyer and some friends of his to have been conveyed by an erupting patient who a few days later in the scabbing stage appeared by strong negative evidence to have been incapable of communicating the disease. Scarlet fever, again, is often apparently propagated by a person whose skin is perfectly clear and normal, but whose naso-pharynx continues affected. The same disease also frequently fails to spread from an actively desquamating patient (though surrounded by susceptible persons) if the mucous surfaces have only been slightly invaded. The points of danger must be determined before personal disinfection can be effectively practised.

Dr. H. J. SPOTTISWOODE CAMERON (Huddersfield) said he hoped Dr. Boobbyer was not going to propose to hand medical men over to some central authority who would be empowered to dictate to them. With regard to the prevention of infection he laid stress on the necessity of making the isolation of the patient complete by removing all infected articles. Quite recently a return scarlet fever case occurred in Leeds. After the return of the isolated patient it was found that a doll which the first patient had played with at the commencement of her illness had been carefully put away till her return. It was given her when she came back, and her little brother who helped her to play with it developed scarlet fever himself. It was not necessary to insist upon the completion of desquamation before the patient returned, but catarrhal conditions of the pharynx, nose, &c., were occasionally overlooked, and mischief resulted. The necessity of isolating enteric fever in hospital was not very generally recognised by the profession. Even professional nurses had been known to treat discharges from such patients very inadequately. A little strong carbolic acid poured over a motion and washed away from it by the flush of the watercloset had been regarded as disinfection. The drains of a town ought never to become infected by typhoid fever. This could only be effected by keeping such imperfectly sterilised motions out of them. Few towns had adequate provision for the isolation of diphtheria; some general hospitals admitted such cases. If the stir which was being made as to the infectiousness of this disease was at all justifiable, surely authorities ought to provide for the isolation and treatment of this terrible disease. It should be remembered that cases were taken into hospital first to treat them, and secondly to protect the public. It was not right to remove patients from their homes under a magistrate's

Digitized by Google

order unless they could be provided with ample air space and other comforts.

Dr. BARWISE (Derby), speaking with reference to the advantage of a large central isolation hospital, said that it would be much cheaper to administer and build than a number of small ones. He could not agree with the suggestion that a five-mile radius should be the extent of an isolation area. It should be at least eight miles, and patients had been safely moved for twelve miles.

Brigade-Surgeon-Lieutenant PRINGLE expressed the opinion that small-pox hospitals were one of the greatest pests of civilisation. If it was necessary to compulsorily segregate every man, woman, and child it was the duty of medical men to see that they had every possible comfort, and that was the only way that confidence on the part of the public could be promoted.

Dr. RICHARDS (Birmingham) continued the discussion.

Dr. FRASER (Chelmsford) described a new apparatus for disinfecting blankets by steam.

Dr. CAVERHILL (Edinburgh) described the use of portable hospitals in Perthshire.

Dr. GOODALL dwelt upon the necessity of cleanliness on the part of nurses and ward servants and the adequate provision of space in the wards.

Mr. GROVES (Bournemouth) referred to the difficulty of getting district councils to expend money in erecting proper hospitals. He advocated the system of one central hospital, and did not see how the case of a patient comfortably placed in an ambulance could be prejudiced when taken six or ten miles any more than if he were taken one.

Mr. HUGH SMITH (Farningham) thought a patient could be removed for from ten to twelve miles without detriment to his case.

Dr. OGILVIE GRANT (Inverness) said he had known a patient to be carried twenty or thirty-five miles without harm.

Dr. BOND (Gloucester) concluded the discussion, and in his reply Dr. BOOBBYER said he was very far from recommending the erection of a central hospital for every individual locality; but in some cases—a colliery district, for instance—considering the facilities there were for the spread of epidemic disease, it would be almost impossible to remove ten to thirty patients a distance of twenty miles. What was required at the present time was instruction, and a great deal of the divergence on important matters of treatment and administrative work was due to lack of information ready to hand. The matter of house disinfection was one in which considerable instruction was desirable at the present time.

The Diagnostic Value of the Diphtheria Bacillus.

Dr. KLEIN, Lecturer on Physiology at St. Bartholomew's Hospital, then read a paper on the above subject. He commenced by laying down the proposition that in the majority of doubtful cases it is possible to decide whether the case is one of diphtheria if in the secretion or membranous exudation of the affected mucous membrane the bacillus diphtheriæ or the Klebs-Löffler bacillus is demonstrable, and that this bacteriological diagnosis is in most instances verified by subsequent events. Those who have had experience, he said, in examining the false membrane of true diphtheria cases, that is, of cases which from a clinical and epidemiological point are at once recognised as such, agree that in some of these cases the superficial layers of the necrosed mucous membrane—that is, of the false membrane—contain large numbers, occasionally in almost pure culture, of one and the same species of bacilli, aggregated in larger and smaller masses, separate, but more often grouped together. These are the Klebs-Löffler bacilli. A second group comprises cases which in clinical and epidemiological respects are undoubted diphtheria, which can be traced to an antecedent case of diphtheria, and in which the membrane or muco-purulent secretions contain a very variable number of the diphtheria bacilli; but they contain at the same time a very large number of other microbes which on cultivation prove to be chiefly cocci, staphylococcus aureus and albus, small streptococci, and chains of larger cocci. In these cases the number of diphtheria bacilli may be sufficiently large to be identified by their shape and grouping and to be easily recovered by culture, or they may be so limited as to be only identified by culture; but even then the chances of identification are not great if the bacilli are practically swamped by cocci—notably, streptococci; in these cases only after careful and extensive searching can the colonies of diphtheria bacilli be discovered, and I am under the impression that it is such cases which have given rise to the opinion occasionally expressed that in some diphtheria cases no diphtheria bacilli have been found. The third group of cases are those in which no obvious antecedent connexion can be established and in which the clinical history does not enable one to make a diagnosis. It is obvious that it is precisely in these cases that correct diagnosis is of the utmost importance. Now, if from the secretion of the fauces (in cases of faucial inflammation, follicular tonsillitis) or from the nose (in cases of rhinitis) diphtheria bacilli can be isolated, then the case must be pronounced to be one of diphtheria. In some such instances, and in conformity with other observers, I have found the diphtheria bacilli at an early stage, and the diagnosis was confirmed by subsequent events—namely, other cases of true membranous diphtheria followed in the same household, and the first individual developed afterwards symptoms of paralysis. Owing to the scarcity of bacilli in some such cases the diagnosis becomes sometimes extremely difficult. These cases are obviously of importance both to medical officers of health, as also to those who ask help from the bacteriologist In such cases occasionally, only by cultivation, and then only by very extensive searching, can colonies of diphtheria bacilli be discovered. In those cases in which, owing to the presence of a great number of other bacteria, chiefly cocci, the ordinary methods of tube cultivation are likely to fail in yielding evidence of the presence of the diphtheria bacilli, the following methods of culture seem better adapted for demonstrating the diphtheria bacilli. If on the examination of stained cover-glass specimens of the membrane or other secretion no definite evidence can be obtained of bacilli morphologically resembling the diphtheria bacilli, and if there are present large numbers of cocci and other microbes, agar plates are made in the following manner. Sterile bouillon agar in a tube is melted over the flame, and then poured out into an ordinary sterile plate dish; after the agar has set a piece of the membrane or secretion is rubbed, by the aid of a platinum loop, gently over the solidified agar surface in the whole extent of the plate dish, and the plate is incubated at 37° C., lid downwards. Next day the surface is found covered and bestrewn, as it were, with minute colonies—in many parts they are so numerous as to lie very close together; now all these colonies are on the surface, none in the depth, because the sowing has been performed on the surface of the agar already set. In an ordinary agar plate—that is, when the melted agar is inoculated, shaken, and poured out into a plate and allowed to set—a good many colonies, of course, come up in the depth and only a fraction on the surface, and it is these latter only which can be subjected to further microscopic and cultural examination; those in the depth are practically lost for such examination. Cultivations on the surface of agar or serum contained in tubes offer likewise great difficulties if very numerous colonies are present, because if amongst a crowd of colonies only a limited number of diphtheria colonies are present these obviously are easily overlooked.

Now these difficulties are overcome by the above surface agar plates, for in these almost every colony can be subjected to microscopic examination. Provided the sowing has been done by lightly rubbing the material over the surface of the agar in the plate all colonies are easily taken off by pressing against the surface of the agar a cover glass, that is, making impression preparations on a series of cover glasses from the agar surface, if necessary from the whole surface; the cover glass impressions are dried and stained; each is found covered with great numbers of dots, each dot being a colony. Subjecting the dots on the cover glasses to an examination with a power of 150 to 300, those that are made up of cocci can be easily distinguished from those made up of bacilli, and each one made up of bacilli can with high powers be readily identified as a colony of diphtheria bacilli by the shape and arrangement. Such plates, after having been used for impression specimens as above, are of no further use; but I think anyone with a little experience could recognise, when examining the agar surface with a magnifying power of 100 to 150, whether a colony is composed of diphtheria bacilli, and if so could under a simple microscope make sub-culture from such a colony. Lastly, there are cases of sore throat and membranous exudations in which even on most careful search no diphtheria bacilli can be recognised by culture. The purulent and membranous exudation in these cases is in morphological respects somewhat different from the true diphtheritic false membrane, inasmuch as it is composed of leucocytes

Digitized by Google

only; it does not contain the reticulated fibrinous matrix constituting the true diphtheritic false membrane; besides, in the former, when examined in the fresh state by means of films, the microbes, though sometimes comparatively limited in number, consist chiefly of cocci, and cultivations do not yield diphtheria bacilli. The cocci chiefly present in these cases are staphylococcus aureus and albus, and particularly streptococci. Such cases are recognised now as cases of pseudo-diphtheria or cocco-diphtheria, though in clinical respects they are not distinguishable from mild cases of diphtheria; as regards their sequelæ they are not difficult to distinguish from true membranous diphtheria, and, as stated before, they do not contain the true diphtheria bacilli. The culture test is also of importance in respect of the disappearance of the diphtheria bacilli from the previously diphtheritically affected mucous membrane or with regard to the presence or absence of these bacilli in the throats of persons that have been attending on, or have come in contact with, diphtheria cases; for if on diligent search by cultivation the bacilli cannot be demonstrated, it may be assumed that they are not present, though one should not be satisfied with a single examination. On the whole, then, the microscopic examination and culture test alone will be found to supply a valuable help in diagnosis, and where necessary it may be effectually controlled by animal experiment.

Dr. HERMANN BIGGS, Pathologist and Director of the Pathological Laboratory, Health Department, New York, discussed the same subject under three heads: (1) he recommended the examination of the throats of healthy persons who had been in contact with diphtheria, or who were inmates of institutions in which diphtheria prevailed, these examinations to be made with relation to prophylaxis, both with a view to the isolation of those in whose throats the diphtheria bacilli were found and to the immunisation with diphtheria antitoxin; (2) he recommended also examinations in cases of throat inflammations for diagnosis; and (3) examinations should also be made at short intervals during convalescence from diphtheria to determine the time of disappearance of the diphtheria bacilli from the throat. In connexion with this discussion he described briefly the methods employed by the New York City Health Department in making these examinations and the technique of the laboratory work. The paper was founded on experience gained from the examination of about 25,000 cultures by the New York City Health Department.

Dr. GOODALL (Eastern Fever Hospital), referring to Dr. Klein's paper, thought it unwise to use the term "pseudo-diphtheria" in cases where a bacteriological examination did not show the diphtheritic bacillus, as it would only give rise to confusion. He wished to ask Dr. Klein whether he had come to any conclusion as to the value of the short variety of diphtheritic bacillus. In regard to the value of a single cultivation, there were a number of cases in which no bacillus could be discovered. This, he thought, might in some way be caused by the method of making this cultivation, whether a swab was used or a platinum wire.

Dr. UNDERHILL wished to know what was the position as regarded notification where there was a total absence of clinical evidence, but where a bacteriological investigation showed the bacillus to be present.

Dr. KLEIN said when the bacilli are present it was perfectly justifiable to diagnose the case as one of diphtheria independently of their length. The virulence did not bear any relation to their length as far as his experience went. Roughly speaking, there were two varieties—one formed small transparent colonies and the other large opaque colonies. Each of these varieties were easily transmitted into the other, but as far as our present knowledge went it was impossible to say whether there were really two distinct varieties. There was no doubt that the use of the swab did make a difference, but he always used the platinum wire. Of course, if a physician sent the swab the best use had to be made of it, but he preferred a piece of membrane or a simple scraping from the tonsils, mucous, &c.

Dr. HERMANN BIGGS here introduced the subject of the value of antitoxin. After quoting some American statistics he concluded: "By the use of antitoxin it has been possible to completely stamp out diphtheria in four great institutions for children in which it was prevailing in epidemic form. In no instance has there been, so far as can be determined, any serious results from the administration of the remedy for this purpose. The duration of immunity is apparently no more than thirty days in many cases."

Dr. GOODALL thought, on the whole, there was no evidence to show that antitoxin had an immunisating power extending over a few days at least.

Dr. NEWSHOLME read a paper on the Extension of the Notification Act, in which he advocated the extension of the schedule of notifiable diseases.

PSYCHOLOGY.

THURSDAY, AUGUST 1ST.

Insanity in Relation to Criminal Responsibility.

The discussion on Insanity in Relation to Criminal Responsibility was introduced by Dr. MAUDSLEY in a paper of great interest, and characterised by breadth of view and vigour of expression. He alluded at the commencement to the repeated attacks that had been made on the law as it at present stands, and especially on the legal criterion of responsibility, which, he said, rested on an unscientific basis, and had been condemned from time to time by eminent judges. Few men, he said, having practical knowledge of insanity would assent to the proposition that an insane person is fully responsible for what he does when he knows the nature of his act, and that it is a wrong act. The sufferer may be tormented with an impulse to do what he knows and loathes as wrong, an impulse so strong that in former times it seemed only explicable as a positive possession by the devil. Yet their theory would have enacted from the man possessed by the devil and dispossessed by himself that he should possess himself all the same and master the devil in him, or else be punished for the devil's doings. We still act in the same irrational way, only substituting disease for devil. The test, he believed, is founded in wrong observation and bad psychology, observation of sane feeling as a measure of insane, and the assumption that reason is the motive force of human action. Reason cannot always control the desire when it knows its good or bad quality, and can appreciate the right or wrong of it. Sir James Stephen would have us say that if a man cannot control himself he does not properly know the nature of his act. Such a test could cut in different directions; it might prevent a madman from being punished for a crime which not he, but his madness, had done, or it might get him hanged for being mad. The test is too metaphysical, even if it were true. Its effect is to bias the judgment of the jury by a prejudgment of facts, and it is a procedure of doubtful legality, inasmuch as it enables the judge to lay down a particular test of disabling mental disease. For are not all the symptoms of mental disease and all the tests of its existence, and of its degree of existence in a particular case, properly facts for the jury? If so, then the imposition of a special test is an interference with the province of the jury and prejudicial to a fair trial. The court could, however, give help to the jury, if it were so minded, by taking means to inform the jury concerning the nature of the particular form of mental disorder in question and the extent of its damaging effect on the mind; or by providing impartial and competent scientific evidence, or by appointing an assessor to appraise the value of conflicting scientific evidence, as is done in a question of navigation. In short, these charges against the present system are: (1) that the court has no more right in law to set up a special test of responsibility in a case of mental disease than to set up a particular chemical test in a case of poisoning; (2) to do this is to give important evidence to the jury without permitting the evidence to be cross-examined or contradicted; (3) the evidence so given is bad, for the test is wrong in fact and based on unsound psychology; (4) it can be made decently workable only by construing it in an unnatural sense and ordaining that words which say one thing clearly shall mean another thing obscurely; and (5) the court makes no provision to secure impartial scientific evidence, but requires or allows the parties in the case to ransack the medical highways and byways in order to obtain contradictory evidence with which to confound a jury ignorant of its meaning. What actually happens now is a condemnation of the present system, for after a person about whose mental state there is some doubt is condemned to death, then competent medical knowledge is summoned to give the impartial help which should have been given at the trial—to undo privately what has been done publicly; and in certain cases medical examination is made into the mental state of an accused person, and he is

Digitized by Google

sent to an asylum and robbed of his right to be tried by a jury. From the legal standpoint the present system is open to criticism. Lawyers think medical men are too ready to discover insanity, and from the conflicting evidence which is brought in a given case—much of it worthless, and which would be rejected by an assessor—they are apt to think that there is no such thing as exact medical science or exact medical honesty. The habit also of discussing responsibility in relation to insanity in the abstract justifies legal criticism, for insanity is no definite and constant entity. Dr. Maudsley then went on to protest against the lamentable extravagances of the latest school of criminology, which "may make the vulgar stare, but make the judicious grieve." A criminal nature which is degenerate is one thing, but to say that all criminals are degenerate and bear the stigmata of degeneracy is another, and a false, thing. Crime should not necessarily be degeneracy. A murderer might be a nobler animal than a Pecksniffian saint, and a murderer on a sufficiently large scale is considered by some a hero. External circumstances must be taken into account in relation to criminals; and in regard to degeneracy, much has lately been done to rob it of definite meaning by stretching it to cover all sorts and degrees of deviation from an ideal standard of thinking and feeling; deviations that are no more serious marks of degeneration than long legs or short legs, long noses or short noses. Words and theories, he thought, should be swept away, facts only regarded, to end the conflict between law and medicine. As witnesses medical men have nothing to do with the right or wrong of the law, although as citizens they may criticise it. The legal test of responsibility has been criticised and condemned for years, but it is not abandoned. It has been condemned by the best, magnified only by the worst judges. The late Sir James Stephen had interpreted it in such a way as to include practically all that medical men ask for. If it really includes (1) knowledge of the nature of the act, (2) knowledge that it is wrong; and (3) control of conduct; it is a pity that all judges do not understand it properly, and that he himself did not take steps to have it tested. Perhaps, although direct and thorough in thought about some things, still in legal matters he loved the good old way of the English mind—to keep the old names when the meaning had been taken out of them, or a new and perhaps opposite meaning put into them, to accept the gradual dissolution of the substance of a belief so long as the label of it was left intact.

Dr. NICOLSON uttered a warning against any alteration in the present law without due consideration.

Dr. URQUHART thought it would be best to have a case referred to the Court for Crown Cases Reserved.

Dr. MERCIER denied that any actual injustice had been done under the present system.

Dr. WEATHERLY said that if justice is done it is only done in the condemned cell, and after the injustice has been inflicted. All judges should have full medical evidence, and it should be remembered that there are many cases, not capital, in which the plea of lunacy should be urged.

Dr. NORMAN KERR remarked on the law as affecting cases of alcoholic insanity.

Dr. SAVAGE alluded to the dangers of the new school of criminology, and stated that all the facts in reference to insanity should be brought out at the trial, and not, after sentence has been passed, on reference to the Home Secretary. It should also be brought out whether the crime is related to the insanity. Although a man was insane enough to believe that the moon was made of green cheese it would be no excuse for his murdering his grandmother.

Dr. CLOUSTON held that actual injustice was committed in condemning a man to death for a crime committed when he was insane, and referred to the more reasonable methods prevalent in Scotland. He protested against the depreciation of criminology as a science. No doubt various absurdities were perpetrated in the name of criminology, but he held that as a science it was capable of much development and usefulness.

Dr. SHUTTLEWORTH referred to the difficulties arising in the case of crime committed by persons of defective development.

Professor BENEDIKT referred to the place alcoholism and sexual perversion occupies in reference to crime.

Dr. YELLOWLEES expressed the opinion that insanity is a matter of degree and that there is such a thing as partial insanity, which should be recognised.

Dr. USHER referred to the mode of procedure in Australia.

Dr. OSCAR WOODS and Dr. DOUGLAS also spoke as to the unsatisfactory character of the law as at present administered.

Dr. RAYNER suggested that a question should be addressed to the Home Secretary in Parliament in reference to each case as it occurred.

Dr. MAUDSLEY briefly replied to the effect that injustice is undoubtedly done by a parade of justice, and urged the abandonment of the right and wrong test.

The Operative Treatment of Idiocy.

Dr. SHUTTLEWORTH read a paper on this subject, in which he expressed a strong opinion against operative measures being undertaken in cases of microcephaly. The premature synapsis he regarded not as a cause of the brain defect, but as an associated defect or perversion of development. In certain cases of local epilepsy and in some cases of hydrocephalus operation might be indicated, and it might also be justifiable in certain cases of congenital syphilitic brain disease.

Dr. FLETCHER BEACH expressed agreement with Dr. Shuttleworth's view that craniectomy is useless for the relief of microcephalic idiocy. He thought, however, it might be useful in some traumatic cases and in cases of hydrocephalus and hypertrophy of the brain.

Dr. TELFORD SMITH referred in a few words to one of the cases related by Dr. Shuttleworth. In this case no less than five operations on the skull had been performed by Professor Horsley. The patient was now less restless and more obedient, but an undoubted idiot, and what improvement was manifested was not more than would be expected as a result solely of the educational treatment that has been employed.

Dr. SHUTTLEWORTH briefly replied.

Insanity of Conduct.

Dr. SAVAGE next read a paper on Insanity of Conduct. He pointed out that there is often more disorder of the conduct than of the speech or writing in the insane. An act may be a symptom of insanity apart from any apparent intellectual defect, but the law takes little cognizance of this. Greater latitude should be given in certificates for the history of insane actions. Moral insanity has a real existence and is a division of the insanity of conduct. Insanity of conduct is seen in some so-called hysterical cases, and the case of a girl was quoted whose insane conduct consisted in the writing of numerous anonymous letters to friends and acquaintances, and also to herself, presumably to divert suspicion, while all the time she was following an apparently normal and correct course of life. It is also seen in poets, inventors, and in many geniuses as a stage of other mental disorder, as mania or melancholia, in degenerative or senile states, and as a result of chronic insanity. It may also occur with some form of so-called monomania, such as kleptomania. On the other hand, there are certain persons whose conduct is perfect, and yet who are defective intellectually, as in the case of a young man of good family, whose outward appearance and conduct were irreproachable, yet who was totally unable to learn to read or write.

Dr. CHARLES MERCIER, who was associated with Dr. SAVAGE in this paper, gave an account of the case of a man who had had a brilliant university career, who afterwards attained a distinguished eminence in his profession, filling several appointments with ability and success, and giving evidence of the possession of exceptional intellectual attainments. At length something happened which compelled him to retire from his profession, and he now eschewed entirely the society of his equals in social standing and lived in a solitude relieved only by the companionship of the family of an old servant, and broken by occasional outbreaks of debauchery and the grossest sexual perversions and excesses. It was impossible to certify him, but after one of his debauches he was in a condition to be certified, and was admitted on an urgency order. The magistrate, however, refused to make a judicial reception order, the signs of insanity due to drink having meantime disappeared. Subsequently he became the subject of an inquisition in lunacy and there being no real opposition on the part of the patient, whose only alternative was a conviction at the Old Bailey, the Master in Lunacy found him insane. His insanity was shown in his conduct, also in the matter of letter writing. This was successively and unnecessarily voluminous; he filled sheets with descriptions of the most obscene and revolting character, and even after he was the prey of blackmailers he allowed letters to come into their hands which increased and strengthened their hold

Digitized by Google

upon him, and he placed himself entirely under the care and direction of a young lad. Besides being manifested in such cases, the insanity of conduct, Dr. Mercier said, is also shown in such cases as those of imperative ideas described in a paper of the late Dr. Hack Tuke, and in conclusion the following propositions were stated for debate: 1. That there are cases in which insanity is evinced by conduct and cannot be established from mental disorder alone. 2. That there are cases in which disorder of mind exists without insanity. 3. That therefore insanity is not essentially a disorder of the mind, nor ought insanity and unsoundness of mind to be used as convertible terms. 4. That our conception of insanity is not complete until it is understood to include as a necessary and integral element disorder of conduct.

Dr. BEDFORD PIERCE questioned whether Dr. Mercier's use of the word "mind" was not too limited.

Mr. CONOLLY NORMAN also said he would prefer to substitute the term "intellect" or "intellectual powers," and he referred to a case in which perpetually repeated acts of bigamy constituted the main evidence of mental aberration.

Dr. HICKS and Mr. HAYES NEWINGTON also spoke, and Dr. SAVAGE and Dr. MERCIER replied.

PHYSIOLOGY.

THURSDAY, AUG. 1ST.

The Physiological Section met in the Laboratory of King's College, under the presidency of Dr. FERRIER.

In opening the discussion on

The Mechanics of the Cardiac Cycle.

Professor J. BERRY HAYCRAFT—whose observations were made in conjunction with Dr. PATERSON—considered that it would be more convenient to limit the discussion to certain definite points. Those selected were: (1) the change in the shape of the heart during diastole and systole; (2) change of position of the heart in the chest; and (3) to inquire whether the papillary muscles acted synchronously with the ventricle. Professor Haycraft pointed out that the inference from the forward movements of the lever, that the diameter of the heart was increased antero-posteriorly during systole, could be shown to be untenable, because a result of the lever sinking into the heart during diastole was to push it out during systole in all directions, which would lead to the absurd conclusion that the systolic heart was increased in all diameters. On the other hand, observation of the frog's heart on measured spaces showed the diastolic heart to be larger than the systolic heart, and a pin in the anterior wall of the heart might be observed during systole to move inwards. Frozen sections were exhibited of the thorax of a dog which showed the relative diminution and expansion of the systolic and diastolic heart. In this connexion the interesting fact transpired that in death by strophanthin, digitalin, barium chloride, and heat the heart died in diastole, contrary to what we know to be the case in the frog. Death in systole was obtained in the dog by the intravenous (jugular) injection of a small quantity of corrosive sublimate. Measurements were given of the systolic and diastolic heart, which showed the former to be smaller in all directions. As regards the position of the acting heart in the chest, it was maintained that gravitation was a potent factor, the heart sinking in obedience to gravitation in any position and springing up from it during systole. This was demonstrated with the limelight shadow of the frog's heart held by forceps. Measurements of the position of the heart at the base, middle, and apex were given. Contrary to those who maintained that the papillary muscles act *after* the ventricle, Professor Haycraft showed that when the attachment to the valve is divided and precautions taken to obviate error the action of the papillary muscles and of the ventricular wall is synchronous. Dr. Paterson and he had found, however, that if these observations were not quickly made that in the dying heart the papillary muscles tended to contract after the ventricle.

Professor FOSTER said that the form of the heart varied, according as it was noted at the beginning, middle, or end of the contracted period. As muscular fibre does not change in bulk during contraction he believed that change in the form of the organ was due to the escape of blood. He asked Professor Haycraft how he explained the fact that when the lever was not pressing on the heart it was thrown up during systole.

Dr. GIBSON of Edinburgh showed tracings from the Conus Arteriosus of a Heart exposed by fissure of the sternum. Auscultation and ocular observation were carried out at the same time in this case. In this case there was antero-posterior increase before expulsion, during expulsion a slight pause, and a double set of vibrations during the second sound. One ventricle ceased its contraction a little before the other, hence the mechanism of reduplication of the second sound. He agreed with Professor Haycraft as to change of position of the heart being due to the position of the animal.

Dr. SPENCER concluded from his observation of two cases in which the heart was sufficiently exposed that there was a considerable twisting movement when the heart acted. He questioned whether the artificial production of systole by corrosive sublimate was not in excess of normal systole, and therefore fallacious.

Dr. PATERSON referred to Hesse and Krehl's opinion as to the importance of the papillary muscles in controlling the valve segments, and argued that this function would be impossible without their action being synchronous with that of the ventricle. He admitted that some twisting movement was observable when the heart acted.

A Member urged that it was evidence of antero-posterior increase during systole that the apex beat was more observable when the patient was placed in the knee-elbow position.

Professor HAYCRAFT, in replying, pointed out that the heart was heavier than the lungs and tended to displace the latter. During diastole in the above position it would fall forward and flatten out, becoming tense in systole, but not necessarily of increased antero-posterior diameter. In reference to Professor Foster's remarks, he said that there might during the first period of systole be a very slight increase, but he was not in a position to give an opinion on the point. During the greater part of systole he believed the antero-posterior diameter of the heart to be diminished. Tracings taken of the frog's heart without the lever pressing upon it showed that the diastolic curve was greater than when the lever touched the heart, but that the systolic rise became a fall.

Trophic Lesions following Section of Sensory Nerves.

ERRATUM.—We regret that in the report of the discussion that followed Dr. Turner's paper upon the Results of Section of the Trigeminal Nerve Dr. Mott is said to have referred to experiments upon the effects of *destruction of the spinal cord*, &c. This is not so. Dr. Mott referred to an important paper which Dr. Sherrington and he had read before the Royal Society, entitled "Experiments upon the Influence of Sensory Nerves upon Movements and Nutrition of the Limbs," published in Vol. LVII. of the Proceedings, a brief abstract of which we subjoin. Section of posterior roots in sufficient number to render a limb *apæsthete*—that is, the "whole series" in the brachial region from the fourth cervical to the third or fourth dorsal inclusive; in the lumbar from the second to the tenth post-thoracic were divided in monkeys, produced a remarkable effect upon voluntary movement of the limb thus deprived of its afferent channels to the spinal cord. "From the time of performance of the section onwards, as long as the animal may be kept, the movements of the hand and foot are practically abolished; the movement of grasping, which is so frequent and useful to the monkey both with the hand and foot, never occurs at all in our experience. On the other hand, the movements at the elbow and knee, and especially the movements at the shoulder and hip, are much less impaired." "The movements which are represented most literally in the limb area of the cortex are extremely severely impaired, and in some instances are entirely abolished." Yet on stimulation of the cortex centri all the movements of that limb are obtained as readily as in the other sensitive limb, thus proving that the pyramidal system has not been injured in the cord. The loss of movement is therefore not due to this cause; whether it is the loss of tonus of the muscles or the absence of all guiding sensations necessary for the initiation and continuance of movement is not determined, but the writers are of opinion from their experiments that the loss of sensibility in the skin and deep structures is of more import than the loss of afferent impressions from the muscles. Dr. Bastian has contributed an important communication upon the subject of this paper to the same volume of Proceedings, in which he differs from the *inferences* of Dr. Mott and Dr. Sherrington, although he accepts the facts. It was also found that if one root to the apex of the limb be left and all the rest

Digitized by Google

divided—e.g., the eighth cervical distributed to the whole extent of the hand—a certain degree of impairment of movement occurs which gradually becomes less; but the impairment often requires careful observation to notice it. Effect on nutrition: Section of the posterior roots in the lower limb was followed after a time by an ulcer on the outer malleolus; section of posterior roots in the upper limb never led to such a change. These facts show, in the opinion of the writers, that the apparent trophic change in the lower limb may more justly be attributed to the liability to pressure and microbic infection. No change in the hand was ever noticed which in the least indicated trophic disturbance. "Wounds accidentally inflicted by the animal itself or its companions on the apæsthete part healed readily when dressed." Other facts of interest are noticed in connexion with the onset of rigor mortis, length of time the motor nerves can be excited after death of the animal, and resulting degeneration.

ANATOMY AND PHYSIOLOGY.

THURSDAY, AUG. 1ST.

Development and Structure of the Placenta.

The discussion upon this subject was opened by Professor ALFRED H. YOUNG, of Owens College, Manchester, who said:

One of the most important features in the development of the placenta is the part played by the fœtal tissues, the fœtal epiblast in particular; and this is the more noticeable as it is opposed to the views hitherto almost universally held. It is true that in the early stages the uterine mucosa increases in thickness, its glands become enlarged and more tortuous, the interglandular substance proliferates, and foldings of its surface may produce crypts. The glands and newly-formed crypts, so well marked in the carnivora, play but a secondary part in the further stages; they merely dilate, and their epithelial lining degenerates and disappears, serving apparently as pabulum for the fœtal tissues. The secondary importance of the glands of the mucosa is emphasised by their fate in the placental areas in rodentia, insectivora, and cheiroptera, in which they undergo little or no increase, and in the later stages are entirely occluded (from the fœtal tissues) by cell elements apparently derived from connective tissue or by endothelial cells. The most important maternal structures are the capillaries; these proliferate and dilate and form a more or less well-marked superficial layer immediately subjacent to the surface of the ovum. The fœtal part of the placenta, on the other hand, is energetic and aggressive. Its epiblast proliferates and becomes greatly thickened and apparently destroys and absorbs the maternal epithelium, though Strahl and Lusebrinck assert that the maternal epithelium persists, though in a changed form, and continues to intervene between the epiblastic cells of the chorion and the deeper maternal tissues.

[Professor Young next referred to the invasion of the uterine mucosa by the epiblast, pointing out how in rodents the epiblastic cells replace the walls of the maternal capillaries. He continued:]

To summarise: the structures which intervene in the placenta between the fœtal and maternal blood streams are not the same in different groups of mammals. Confining our attention to the two groups which have been most thoroughly investigated we see that in the carnivora the fœtal blood is separated from the maternal by three layers: (1) the endothelium of the maternal vessels; (2) a layer of fœtal epiblast, which generally contains two rows of nuclei and is not divided into cell areas, but is of the nature of a plasmodium; and (3) the endothelium of the fœtal vessels. In rodents, however, according to Duval's observations, there may be only a single intervening layer separating the two blood streams, and that is the endothelium of the fœtal vessels. We thus arrive at the following conclusions concerning placental development and structure: 1. Fœtal tissues play a most important part in placental development; they invade, destroy, and devour maternal substance. 2. The maternal tissues pass through three phases; they exhibit a remarkable activity before the fixation of the ovum. This is succeeded by what may be looked upon as an irritative proliferation due to the invasion of fœtal epiblast, and finally they disappear in great part coincidently with the epiblastic advance. 3. The relationship between the fœtal and maternal blood streams may be much more intimate than has usually been believed; and in any case the intervening structures are chiefly fœtal. 4. The uterine glands and crypts play a comparatively unimportant part in the placental area; they are not penetrated to any great extent by fœtal villi, but their epithelium degenerates and disappears, and is utilised as fœtal pabulum, except at their terminal extremities, where it remains almost unchanged to serve for the regeneration of the surface after parturition. These general facts, which have been established by observations on lower mammals, enable us to form a fairly definite conclusion regarding the layer of epithelium which forms one of the intervening strata between the two blood streams in the human placenta, and there can no longer be any doubt of its fœtal origin; it is certainly fœtal epiblast.

[Professor Young then proceeded to consider the formation of the allantois, and continued:]

In the meanwhile it is evident that there are many points relating to the development and structure of the placenta which may well be discussed both by the embryologist and the histologist, and beyond this also by the pathologist and the gynæcologist, who will find in the developmental history of the placenta the keynote to many obscure problems of uterine and placental disease. One cannot, e.g., fail to observe the remarkable similarity between the early stages of placental formation and those seen in the development of malignant epithelial tumours. In both there is epithelial proliferation followed by epithelial invasion and accompanied by irritative phenomena in surrounding tissues. During placental formation the maternal tissues are invaded by fœtal epiblastic cells much in the same way that the subepithelial stratum of skin or mucous membrane is encroached upon by proliferating epithelium in cancer formation, and it would not seem impossible that normal placental epithelial changes might, under certain circumstances, lead to true carcinoma. There can be little doubt that the fœtal epiblast grows at the expense of the maternal tissues, and there seems no reason why any portions left behind on the separation of the placenta should not continue to grow and, invading still further the uterine mucosa, assume all the characteristics of a definite tumour growth. I ventured to draw attention to this point in a paper read before the North of England Gynæcological Society some three or four years ago, and I then referred to the most interesting case recorded by Dr. H. Meyer of an epitheliomatous growth which followed the removal of a hydatiform mole. The epitheliomatous character of the new growth was clear, and the resemblance of the invading columnar processes to chorionic villi, as previously pointed out by Professor Klebs, was apparently fully recognised; but nevertheless Dr. Meyer suggests that the epithelial element was probably of maternal origin and that into it chorionic villi had protruded. This, however, does not seem a probable sequence of events, whilst the changes which are known to take place in the development of the placenta give strong support to the view that the epithelial element was in all probability fœtal. This, again, is emphasised by a similar case described by Fränkel as "carcinoma developing from the chorionic villi." This case was one of malignant disease of the corpus uteri following the removal of a vesicular mole. "The growth had a papillary form, invaded the deeper tissues, and gave rise to metastases. Microscopically it was shown to have originated from the remnants of chorionic villi left after removal of the mole, since the structure of the uterine glands was still recognisable, and its histological appearance was quite different from that of cancer of the corporeal endometrium." That uterine tumours may originate from placental relics is fully recognised by Hartmann and Toupet in their valuable memoir on the "Later Evils Following Retention of Placental Relics." Dr. Eden, in a preliminary communication on the development and normal structure of the placenta, states that the large decidual cells are really epiblastic cells, and if this is so the sarcomatous character of the tumour becomes more than doubtful. Clearly the study of abnormal conditions occurring in connexion with placental formation should be based upon accurate observations on the development and structure of the normal placenta. With a fuller knowledge of the structure of the placenta and of the exact relationship of the fœtal and maternal blood streams we shall understand better the important question of the transmission of disease between mother and fœtus. In short, a wide field for experimental observations will be open, and it is by such observations alone that we can hope to obtain satisfactory results.

Mr. ROBINSON, Mr. LOCKWOOD, and others, including

Digitized by Google

the PRESIDENT took part in the discussion, and Professor YOUNG showed a very complete series of embryonic sections under the microscope.

Mr. MANNERS SMITH read a paper on the Anatomy of three Symmelian Monsters, illustrated by sketches of the examples in question.

Mr. PARSONS and Mr. ROBINSON discussed the subject, and the latter inclined to the theory that arrested development is the essential cause of the deformity rather than a tendency of parts to fuse which Mr. Manners Smith supported.

A paper by Dr. GRIFFITHS was read on the Anatomy of the Genito-urinary Apparatus of the Pig and Boar, and showed that castration exerts an all-important influence on the growth and development of the accessory sexual glands, and that the full development of striped muscle around the urethra is dependent on the full development of the testes.

FRIDAY, AUG. 2ND.

The Topographical Anatomy of the Abdomen.

A discussion on this subject was opened by Professor THOMSON of Oxford University. After referring to work done by Mr. W. Anderson and Professor Cunningham on this subject, Professor Thomson reviewed the present systems and criticised the generally accepted one as put forth in Quain's Anatomy, in which the nomenclature of the regions does not correspond to the regions proper. In hopes of forming a new system the following fixed points were taken: (1) the centre of the articulation between the lower end of the sternum and the ensiform cartilage; (2) the anterior superior iliac spines; (3) the most dependent part of the tenth costal arch; and (4) the symphisis pubis. Of these the costal arch is the most unsatisfactory on account of its variability; but for want of a better substitute Professor Thomson determined to adopt it. By joining the given point on the sternum with the point corresponding to the anterior-superior spine of the ilium a triangle is formed the base of which corresponds to a line joining the two spinous processes, and called the inter-spinous line. A transverse line is also drawn through the most dependent part of the tenth costal arch and called the subcostal line. The importance of the middle line was also pointed out, which, although continually employed in clinical work, has not before been made use of in this country for anatomical delineation. Further explanation was also given for applying this system to mapping out the regions from the back, and some German systems were criticised, especially with regard to curved lines, which Professor Thomson thought should never be used.

In the discussion which followed Mr. MAKINS remarked on the utility of the outer border of the rectus muscle as a surgical guide. Mr. LOCKWOOD thought that all artificial lines should as far as possible be done away with, and use made only of natural lines and points. Mr. W. ANDERSON thought the drawback to any new plan was the difficulty in getting it universally adopted. Professor THANE, Dr. WILBERFORCE SMITH, and Dr. BLACK also joined in the discussion, after which Professor THOMSON replied.

Synostosis of the Pre- and Meso-sternum.

Twelve examples of this condition were quoted by Dr. KEITH, four of which were in negroes or negroid people. It is much more frequent in anthropoids than in man, and the variation may be called one of anthropoid character, and its occasional occurrence among men, gorillas, or chimpanzees may be variously interpreted. It may be regarded as indicating only a developmental aberration brought about by unknown circumstances, or it may be supposed that the ancestors of man, the gorilla, and chimpanzee were, like the gibbon, adapted for brachiation as a chief means for progression. Dr. Keith did not, however, think that the occurrence of such a variation as this in the various genera of the anthropoidea necessarily indicated community of descent.

Mr. GRAVES STOKER showed an interesting specimen of a floating liver.

Mr. HIGGINS gave a demonstration on the mechanism of the knee-joint, and illustrated by specimens the various points of contact in different positions of the joints.

Mr. STANLEY KENT showed by means of lantern-slides the anatomy and histology of the genital organs of an hermaphrodite dog, in which both sets of organs were very fully developed.

PATHOLOGY.

THURSDAY, AUG. 1ST.

Peripheral Neuritis.

The debate on this subject was introduced by Dr. SEYMOUR J. SHARKEY, physician to St. Thomas's Hospital. He said: Peripheral neuritis has only engaged the attention of our profession in recent years. The symptoms produced by the disease have long been known, and Graves even suggested in a very pointed manner that they had their origin in disease of the peripheral nerves; but it was only in 1864 that definite proof was given by Dumésnil that such a pathological condition was the cause of the symptoms in the disease now named peripheral neuritis. As might be expected when a new field like this was opened up, a very large number of conditions previously not understood were attributed to this cause, and it can scarcely be doubted that the list of diseases at present referred to inflammation of the peripheral nerves will have to be curtailed. The subject, indeed, is still in its infancy, and many conditions which are supposed to be due to peripheral neuritis have not yet been proved to be so. Any member, therefore, of this Association who can afford fresh proofs of the existence of neuritis in disease will make a welcome addition to our pathological knowledge. It would be well to consider, too, whether we have not been trying to draw too sharp a line between the peripheral and the central nervous system; whether we have not been too anxious to limit the pathology of many of these diseases to the nerves, while the various agents which produce them cause alteration in the centres as well. Such poisons as alcohol and lead, the poisons of acute specific diseases such as influenza, and many others too, are certainly productive of widespread central changes, at the same time that they specially affect the peripheral parts of the nervous system. One of the most important points for discussion is, in my opinion, the legitimate use of the term "peripheral neuritis." What anatomical changes do we consider as proof of inflammation? Are we justified in speaking of a change in nerves as inflammatory in the absence of those vascular phenomena which are usually looked upon as proof of inflammation? In reading the reports of cases of peripheral neuritis it will constantly be noticed that the pathological condition found post mortem was segmentation and breaking up of the medullary sheath and nothing more. This is called "parenchymatous neuritis." In other cases nothing at all is found to prove what the nature of the case was, but it is argued from the presence of some of the symptoms that occur in undoubted neuritis that the disease is neuritis. Would it be more correct to speak of peripheral nerve intoxication where the post-mortem find is negative, as in rapidly fatal cases of Landry's disease, for example; of peripheral nerve degeneration where the only change is breaking up of the white sheath of Schwann; and of peripheral neuritis when the vascular phenomena of inflammation are present as well? The granular degeneration of muscles, whether fatty or albuminous, and that of many cells in the body, such as those of the liver, is not the result of inflammation only. Why, then, should breaking up of the medullary sheath into droplets be called neuritis? It may or may not be true (and this is a question with regard to which we might hope to elicit some fresh information) that we cannot separate clinically the cases where the medullary sheath is broken up from those in which an inflammation of the fibrous sheath of the nerve is evident as well. Still, it may be possible to do so some day. If this distinction between nerve degeneration and nerve inflammation were made, many cases now termed neuritis would receive a more reasonable explanation as cases of degeneration—such cases, for instance, as are now sometimes classed as "dyscrasic peripheral neuritis" being found in cases of anæmia, cancer, senile conditions, &c. While we are considering the propriety of separating cases of nerve degeneration from cases of nerve inflammation a very important question suggests itself. Have the changes which the peripheral nerves undergo after death been carefully investigated? Are they not principally changes in the medullary sheath, and changes resembling those attributed now to parenchymatous neuritis? One reads of cases where parenchymatous neuritis has been observed post mortem, though there was no clinical evidence of disease of nerves during life. In such cases the suspicion naturally arises in the reader's mind that post-mortem changes may have been mistaken for pathological conditions. Any pathologists who can contribute definite information as to the changes which occur

Digitized by Google

after death in the peripheral nerves, and particularly as to the rapidity with which they occur, will have made a very important contribution to this discussion. It is a somewhat remarkable thing that in multiple neuritis the terminal portions of the nerves are nearly always first affected. Why is this? May it be partly because they are so delicate in structure, partly because in their peripheral ramifications they cover a much larger area than they do when collected into bundles, and so are more exposed to the poison circulating in the capillaries; partly, perhaps, because they are furthest removed from the nerve cells on the energy radiating from which their health certainly depends? Another very interesting point is the special affinity which certain poisons seem to have for certain nerves. It is true that in cases of intense or prolonged poisoning the effects on the nervous system may be very widespread. Yet it is none the less true that in alcoholic neuritis the extensor muscles of the limbs, and especially of the legs, almost invariably first fall a prey to the poison; in lead, the extensors of the fingers and wrists; in diphtheria, the muscles of the throat and internal muscles of the eye. Still more remarkable is it that the selective power of these toxic agents may exert itself on the motor filaments or on the sensory almost exclusively. In lead-poisoning, for instance, sensory alterations are hardly complained of at all, and the same is often true of diphtheria, whereas in cases of alcoholic neuritis a stage of the most acute sensory disturbance may long precede the advent of paralysis. Indeed, there is some ground for supposing that even the trophic and vasomotor nerves may be specially picked out in some cases. The pathology of Raynaud's disease is not yet satisfactorily established; but there are certainly grounds for supposing that the remarkable vascular and trophic changes which characterise this affection are the result of disease specially affecting the vascular and trophic nerve filaments or the centres from which they radiate. Can anyone throw light upon the meaning of these interesting phenomena? The electrical reactions of nerves and muscle are frequently altered in the diseases under consideration, but it cannot be said that we yet know as much as we might about the value of the so-called reaction of degeneration. The alterations which occur are very variable, sometimes being but slight, sometimes profound. In the latter case they indicate, no doubt, a very marked disorganisation of nerve and muscle. But what do the slighter changes indicate, or even their absence, as regards the pathological changes in the nerves? Can they be utilised for the purpose of distinguishing between nerve intoxication, nerve degeneration, and nerve inflammation? The discovery of neuritis as a definite pathological condition has led to the removal of many paralytic affections from the category of spinal cord diseases. We now place them under the heading "peripheral neuritis." For the diagnosis of these affections we have relied largely on the simultaneous involvement of motor and sensory functions, as proving that a disease which produces paralysis and atrophy of muscle cannot be due to an affection of the anterior cornua of the cord only. But now that it has been shown that these atrophic paralyses can result from disease of the peripheral nerves when the motor filaments are specially picked out the question must be asked: Have we any means at present at our disposal which enables us to distinguish between anterior cornual disease and peripheral nerve disease? Again, cases of paraplegia due to an extensive affection of the spinal cord, in which, nevertheless, there is no alteration in sensation, are not uncommon, and similar affections of the spinal cord and its surroundings may result in paraplegia with pain and sensory disturbances. How can we distinguish such diseases of the spinal cord from peripheral neuritis? We have generally relied upon the presence of an affection of the sphincters in the former and its absence in the latter. This, however, is not a safe criterion. I have myself lately had a case of painful paraplegia under my care in which the sphincters were involved, and in which nothing was discovered at the post-mortem examination. On microscopic investigation of the nerves proceeding from the pelvis an intense neuritis was found. We have, therefore, to consider how we can advance the diagnosis of these conditions in order to put it on a level with our present knowledge of the pathological changes which lie at the root of them. Another question which needs discussion is that of the cause of the peripheral neuritis and muscular atrophy which occur in association with joint disease. This has not yet received a satisfactory explanation. Is it due to some reflex effect on the cells in the nerve centres which preside over the nutrition of these muscles; or is it a secondary local effect of the inflammation of joint; or do both the neuro-muscular and joint changes own a common cause? The significance of the absence of the knee-jerk, which occurs in many cases of diabetes, together with the occasional presence of other symptoms suggestive of alteration in the peripheral nerves, is worthy of further consideration. Are these phenomena due to nerve intoxication produced by some poison manufactured in the body by disease? Are they the result of simple degeneration of nerves and breaking up of the medullary sheath, or do they owe their origin to genuine peripheral neuritis? Again, can anyone produce further evidence of the cause of Raynaud's disease? The fact that tetany has also been attributed by some to peripheral neuritis suggests another question, Does peripheral neuritis give rise to spasmodic affections? As a rule it certainly does not, but the cramps, muscular twitchings, tremors, &c., of the earlier stages of alcoholic neuritis suggest that spasm may possibly sometimes result from peripheral changes in the nerves. I would ask, however, whether a prolonged tonic spasm is not more likely to be caused by changes in nerve centres than by changes in nerves? We might hope to have this question answered by pathological anatomy, but it is far from improbable that a nerve intoxication may be the cause of tetany and may leave no alterations in the neuro-muscular apparatus which are capable of demonstration by our modern methods of examination. Up to the present time most of the observations and investigations which have been carried out for the elucidation of the subject of peripheral neuritis have dealt with disease of the cerebro-spinal nerves. The vagus is not infrequently diseased and gives rise to marked and even fatal cardiac disturbance. A few observations have shown that the terminal distributions of nerves in the substance of the heart are liable to alterations which probably play an important part in some cases of serious cardiac disease. But if it has been shown that few, if any, of the cerebro-spinal nerves are exempt from pathological alterations resulting in sensory and motor disturbance, is it not probable that the sympathetic nerves may be equally vulnerable? May not many of the so-called functional disturbances of the viscera, with their neuralgias and disorders of secretion and metabolism, owe their existence to temporary nerve intoxication, to nerve degeneration, or to nerve inflammation? Here is a wide field, indeed, for investigation, and communications on this point would be welcomed by all pathologists and physicians. In the short space of time which has been allotted to me for the introduction of this debate I have called attention to a few points upon which I, at any rate, would like to hear the views of others. But the disease "neuritis" suggests a far larger number of questions of interest than have been touched upon, and questions, too, which may appear of greater importance to those who have a special knowledge of this subject. No one can desire that the contributions made by members to this discussion should be limited to the few points raised by the person who introduces it. All additions to our knowledge, all criticisms of current theories, to whatever points they may be directed, will, I feel sure, be warmly appreciated by those who have honoured this Section by their presence.

Dr. W. M. ORD drew attention to the concurrence of gastric ulcer with anæmia. He had observed many cases of anæmia in which there were signs of organic lesion in the heart of the nature of endocarditis or pericarditis, but in which there was no antecedent history of chorea, acute rheumatism, or fever, and that these were associated with clinical symptoms pointing to gastric ulcer. For some time he had only had clinical evidence of these phenomena, but he now knew of two such cases in which necropsies had been performed and which revealed a gastric ulcer in the stomach with vegetations on the cardiac valves. He thought that possibly the ulcer produced disturbance of the nutrition of the heart in some reflex manner, or possibly both were due to some common cause, which latter perhaps was the more likely of the two suppositions; he hinted that this might be explained by a disturbance in the nutrition of these parts by some nerve lesion. He was also of opinion that the circular form of gastric ulcer was *per se* suggestive of a possible neuritic origin analogous with the bullæ found on the skin in certain nerve lesions.

Dr. RUSSELL WELLS, in continuing the discussion, read a short paper on the Changes met with in Nerves due to Post-mortem Degeneration. The paper detailed the results of researches conducted by him in conjunction with Dr. W. H.

Digitized by Google

Wilson. After recalling the observations of other investigators on the microscopical appearances met with in the peripheral nerves in neuritis, he drew attention to the fact that in patients dying from various lesions in other organs quite apart from the nerves—such as pneumonia, morbus cordis, and acute fevers—the appearances of the medullary portion, as seen under the microscope, varied according to the time after death at which the preparation was made and to the length of the period during which it was kept in preservative fluids. The earliest changes which he found were breaking up of the medullary sheath and variations in the readiness with which the nerve fibres stained with reagents: the latter, he thought, was due to loss of the medulla in places, and this again to be caused by post-mortem chemical changes: the axis cylinders did not take part in these changes. The loss of the medulla leads to the nerve simulating the appearances of ordinary connective tissue. Specimens of this kind are indistinguishable under the microscope from nerves taken from cases of neuritis. He added that he had not seen as a post-mortem change rupture of the axis cylinder which writers on neuritis describe as occurring in that affection. However, he was of opinion that the changes met with in neuritis were not always due to post-mortem decomposition, because in the case of animals in which neuritis had been produced artificially the nerves would doubtless be examined immediately they were killed, and yet the nerves showed alterations in structure.

Dr. MOTT thought that peripheral neuritis was of interest in view of the theory of Marie that it is due to modifications in the ganglion cell with which the nerve is in anatomical continuity. That in diphtheria changes occur in the cells of the anterior horn as well as in the nerves, and that the paralysis was in some instances permanent and associated with wasting, was in favour of this view. He was of opinion that the reason why alterations in structure occurred in the end plates of motor nerves in peripheral neuritis was their remoteness from the seat of nutrition in the ganglion cell. Incidentally, he mentioned his inability to find degeneration in the end plates in two cases of diphtheria in which he had made observations for that purpose. Fibrous tissue met with around the nervous tissue in various cases of nerve degeneration he believed to be secondary to that degeneration. For his part he thought that in diphtheritic and other forms of peripheral neuritis the poison acted primarily on the nerve cell.

Dr. ORMEROD thought that, besides peripheral neuritis being due to primary disease of the nerve fibres on the one hand, or of the nerve cells on the other, there was probably a *tertium quid* in which both cells and nerve fibres were simultaneously affected. He suggested that, as Dr. Jackson had shown that the smaller nerve cells were more likely to be affected than the larger by poison, similarly the smaller terminal fibres were more readily affected than the larger trunks.

Sir T. GRAINGER STEWART made some remarks concerning the history of peripheral neuritis, and then went on to say that he thought that an affection of peripheral nerves was the only explanation of the combination of the motor, sensory, and nutritive changes met with in this disease. He thought the following clinical points were worthy of note—(1) that so marked a lesion could be entirely recovered from; (2) that an affection of peripheral nerves formed a ready explanation of the passing paralyses met with in the early stages of locomotor ataxy; (3) the capriciousness of neuritis in the selection of nerves; and (4) the not uncommon deaths in this disease due to the involvement of vital nerves. He mentioned the superiority of hypodermic injections of strychnia, as soon as the first acute stage was passed over, to its internal administration.

Dr. HAMILTON, Professor of Pathology in the University of Aberdeen, questioned the correctness of the nomenclature in peripheral neuritis, and added that as a result of his experiments in the artificial production of inflammation in nerve tissue he believed the appearances were entirely due to degenerative changes, and not to inflammatory processes at all.

Dr. SAUNDBY (Birmingham) disagreed with Dr. Hamilton's view that in many cases the changes were in reality due to inflammation of the nerves. He drew attention to the tenderness which occurs over the nerve trunks in certain forms of neuritis, as well as to the swelling of them which accompanies it.

Dr. GOODHART and others joined in the discussion, and Dr. SHARKEY briefly replied to the various speakers.

Vaccinia and Variola.

A discussion on this important subject was opened by Dr. S. MONCKTON COPEMAN, Medical Inspector of the Local Government Board and Lecturer on Public Health at Westminster Hospital. Dr. COPEMAN said: Before referring to the most recent work on the pathology of variola in detail it may be well to briefly recapitulate the subject matter of the paper which I had the honour of bringing before the notice of this section at the meeting of the Association held last year at Bristol. I there stated that the main dispute with reference to the pathology of vaccinia has always centred round the term variola vaccina, "small-pox of the cow," given to the disease in the first instance by Jenner. Consequently, the important question remains as before, whether vaccinia is or is not one with small-pox. In my former paper I stated that the problem has been attacked from two separate points of view—(1) experimental work having for its object the production (if that be possible) in the bovine animal by inoculating it with small-pox lymph of a disease indistinguishable both in its immediate local and in its subsequent general effects from true vaccinia; and (2) microscopic pathology and bacteriology, including, I may add, the testing of bacteria derived from lymph also on the bovine animal.

[Dr. Copeman then referred to the work which had been done with regard to the production of vaccinia by "variolating" bovine animals. He continued:]

As far as I am aware the most recent experiments of this nature which have been carried out are those of Dr. Klein and myself, the results of which have been published in full in the reports of the medical officer to the Local Government Board and in the *Journals of Pathology* and *Bacteriology* respectively. I do not, therefore, propose on the present occasion to refer to those experiments in detail, but I may perhaps add that in my own experiments at any rate no question of possible contamination with vaccinia can possibly arise, seeing that all my work was conducted at the Brown Institution; that as a special precaution new scalpels were used, which were invariably first sterilised in a flame; that before and after use the table was thoroughly washed with carbolic acid and water, and during the intervals of use kept exposed to the open air. As the result of all the work which has been done in this direction there can, I think, at the present time be no reasonable doubt as to the possibility of inoculating the calf with variolous matter, with the result of producing thereby, after one or more removes, a malady which is certainly no longer small-pox as ordinarily understood, seeing that it has now completely lost, when transferred to the human being, its original property of infectiousness. [Dr. Copeman here cited the results of various experiments upon monkeys.] Turning next to the micro-pathology and bacteriology of variolous, and more especially of vaccine lymph, I was able to bring forward certain evidence bearing on the important subject of the storage and preservation of vaccine lymph, as also on the relationship of variola and vaccinia so far as microscopic and bacterioscopic examination of lymph can help us. These two subjects I desire particularly to consider on the present occasion. It is a matter of common knowledge that vaccine lymph, whether stored in the liquid state or freshly obtained from a normal vesicle, usually is found when examined bacterioscopically to contain micro-organisms of various kinds, which have been shown by Crookshank, myself, and by other observers to be for the most part mere saprophytes.

[Dr. Copeman mentioned the use of glycerine in destroying these saprophytes and the streptococcus of erysipelas. He continued:]

With reference to possible transmission of syphilis and tuberculosis by calf lymph I need say nothing, seeing that it is universally admitted that the first of these two diseases is not transmissible to the calf, and that the bacillus of tuberculosis has never been discovered in vaccine lymph, bovine or human. In consequence no doubt of the apparent impossibility which existed until recently of isolating any bacterium from vaccine lymph which could be regarded as specific to vaccinia, several observers have sought to prove that organisms of a somewhat higher order than bacteria might be concerned in the production of this malady and also of variola. In this connexion it may be mentioned that bodies believed to be of the nature of psorosperms or sporozoa have been described as existing in the vaccine vesicle by Guarnieri and Pfeiffer on the Continent and by Dr. Armand Ruffer

Digitized by Google

and Mr. Jackson Clarke in this country. But as to this I was taken to task last year by Dr. Ruffer for mentioning the organisms described by Guarnieri and himself in the same category with those the occurrence of which had been put on record by Pfeiffer and Mr. Jackson Clarke. As, however, the last-named gentleman is to bring forward a paper giving the result of his researches, I do not propose to deal further with this subject on the present occasion, except to put on record the joint opinion of Dr. Klein and myself to the effect that, whatever may be the exact nature of these so-called sporozoa, they have not yet been proved to have any causal relationship with the diseases in question. On the other hand, as I stated last year, Dr. Klein and I have concurrently—though quite independently—shown that in specially stained specimens of vaccine lymph, taken at a period antecedent to full maturity of the vesicles, minute bacilli can be demonstrated, often in considerable numbers and in practically pure culture. These bacilli cannot be found, or only with difficulty, in mature lymph, for the reason probably that they have by then given place to spores. For some time it appeared impossible to obtain further evidence as to the *rôle* of these bacilli, as they altogether refused to grow on any of the ordinary culture media and under either aerobic or anaerobic conditions, though this very fact obviously tends to show that they are not of a merely saprophytic nature; during the past year, however, certain experiments which I have devised appear to prove that it is possible to obtain a growth of these bacilli in a particular culture medium, and even to carry on such growth in secondary cultivation. As it seemed to me, the desideratum for the purpose of inducing growth of the supposititious micro-organisms was a medium which had not been artificially sterilised, which *a priori* should afford the necessary pabulum, and which at the same time, whether it was to be considered aerobic or anaerobic, was secure in its circumstances against contamination. Hence the choice appeared to lie between the intra-peritoneal fluids of one or another living animal and the hen's egg, which has already been made use of as an alternative culture medium. As regards intra-peritoneal fluid I foresaw difficulty in that it is apt to contain leucocytes, which might easily vitiate experiment; and accordingly I adopted the hen's egg as a matter of first instance. I had no experience to guide me as to the best method of carrying out the inoculation of the egg, or of the period of incubation best suited for the object I had in view, and my attempts for a time, therefore, met with but small success. My inoculations were carried out by first cleansing the surface of the egg with corrosive sublimate solution and afterwards with alcohol, and then breaking a small hole in the shell by means of a sterilised needle and forceps. Through the opening thus made I mixed the yolk and albumen of the egg by means of a platinum needle, and then carried out the inoculation by means of a glass capillary pipette which had recently been drawn out in the blow-pipe flame. For the purpose of such inoculations I employed variolous crusts obtained from the small-pox ships of the Metropolitan Asylums Board. These crusts were rubbed up in a small glass mortar with a minimal quantity of sterilised normal saline solution. Of the resulting creamy emulsion a drop or two was then taken up into the glass pipettes and the inoculation carried out. Finally, the small hole in the egg was closed up either by means of a small pledget of sterilised cotton-wool soaked in collodion or with melted sealing-wax. The eggs inoculated in this manner were then placed on beds of cotton-wool and kept in the incubator at a temperature of 37° C. Here they were left for varying periods of time, a month being the period which was eventually found to be that which was most desirable. On opening an egg thus treated I found that in its interior was contained a creamy material which in great part had replaced the ordinary egg contents. This material examined as cover-glass specimens appeared to be a pure culture of one organism only—viz., a bacillus which morphologically was not to be distinguished from the bacillus which I have previously described as to be found in early vaccine lymph. My next step was to attempt to grow it in subculture and to make observation also of the effect of its direct transference by cutaneous inoculation into the calf. As regards attempts at subculture in all the media most usually employed for such a purpose, including gelatine, sugar gelatine, agar, glycerine agar, sugar agar, and serum, these were unsuccessful, as subculture of the bacilli contained in vaccine lymph had always failed when the ordinary culture media were adopted; but with the calf it was different.

On March 28th, 1895, Calf A was inoculated by eighteen incisions (fifteen on the abdomen and three on the scrotum) with a small quantity of the creamy emulsion contained in Egg No. 5, which had been incubated for one month after inoculation with small-pox crusts, as already described. On the 30th scrapings were taken from the vesicular points which had appeared in the line of two of the abdominal incisions, and also from one of the incisions on the scrotum, which had become slightly raised and red. With material thus obtained Calf B was on the same day inoculated by six linear incisions on a specially shaved area on the abdomen. Three incisions were inoculated with scrapings taken from vesicular points, and the other three with scrapings from the incision on the scrotum of Calf A. Three days later, on April 2nd, all six insertions appeared to be taking, though eventually one died away. On the 4th the calf was photographed, and on the same day a child was vaccinated from it by Dr. Cory. This child I have since seen. It has five good marks, and the mother told me that the vaccination "did splendidly" and that she had had no trouble with the child.

On March 28th, 1895, Calf C was inoculated on the right thigh in twenty-four insertions with emulsion from Egg No. 5, which had been kept in a pipette since the first calf of the series was done. By April 2nd three small vesicular points had appeared in the line of as many of the incisions. With scrapings from these I vaccinated myself, and Dr. Cory vaccinated a child aged three months. The process in my own case had aborted by the fourth day, but the child "took" quite normally and had when inspected on the eighth day five good vesicles with very little areola. On April 2nd also Calf D was inoculated from the small vesicles on Calf C in ten incisions on a special area of the abdomen. These all showed on the fifth day vesicles not to be distinguished from those of like age arising from the use of current lymph on the same animal. On May 7th, 1895, Calf E was inoculated on a special shaved portion of the abdomen in twelve incisions from the contents of Egg No. 5, taken into a pipette on the previous day. On the 14th six small vesicles, which had appeared in as many of the lines of incision, were clamped and scraped, and the material thus obtained was employed on the same date for the inoculation of Calf F in twelve insertions. On the 18th six of these insertions had taken well. On the 21st eleven of the twelve incisions showed a wide crust surrounded by a vesicular ring. The width of the crust was apparently due to the calf having been able to lick the places, as its collar had been removed by mistake on May 18th. Two of the more markedly vesicular of these "places" were clamped and scraped, and with the material thus obtained Calf G was inoculated by twenty insertions on a special area of the abdomen. By the 28th all the twenty insertions made had "taken," and no appreciable difference could be made out between the vesicles which had arisen on the site of these incisions and on those which at the same date had been inoculated with current lymph. This calf was twice photographed by Mr. Kent. From Calf G, Calf H was inoculated on the 25th; and, further, this strain of variola-vaccine derived in the first instance from the egg culture was carried on through two additional removes in the calf, after which it was not further cultivated. On May 28th, 1895, lymph taken from vesicles at the third remove from the egg culture were in my absence employed by Dr. Cory for the vaccination of a large number of children at the Animal Vaccine Establishment, owing to the fact that for some reason or other the current strain of lymph had failed to give good results in the two calves which had been vaccinated according to the usual routine. All these children showed excellent marks when inspected a week later, and several of them were photographed by Mr. Kent. Interesting, and indeed satisfactory, as are these experiments from my point of view, I do not claim for them demonstration of the practicability of growing and multiplying outside the animal body, in artificial media, the particulate cause of small-pox, or of converting the latter by my processes into the essential cause of vaccinia. And for this reason: these experiments of mine on the bovine animal had to be conducted, at any rate in this preliminary stage, at Lamb's Conduit-street, and the subjects of them had to be calves that on each occasion of experiment by me were at the same time vaccinated in some part of their bodies with the calf lymph current at this station. It is true that every precaution was taken in the

Digitized by Google

way of sterilising instruments and cleansing operation-tables, in selecting a given, clearly defined area on each animal for insertion of my lymph, and for keeping the incisions made by me protected as far as possible against later accidental mediate inoculation with lymph from some part of the same or other calf into which animal vaccine-establishment material had been inserted. Nevertheless, it is possible that, in spite of all precautions, accidental inoculation of my incisions with animal vaccine-establishment lymph may have occurred; and, further, I am not able to deny that simultaneous inoculation of the calves with my egg culture and with ordinary vaccine lymph may have in some occult way influenced the manifestation witnessed on the areas wherein my egg lymph was inserted. So, of course, these experiments have to be repeated, and are, indeed, in course of repetition. They involve repetition of the process from its very beginning—i.e., direct inoculation of the hen's egg with crusts of variola with calf lymph or with human lymph; tests by subculture in ordinary media and in the egg of any pure growth of microbe thus obtained, and inoculation of the calf elsewhere than at Lambs Conduit-street, both with the primary egg cultures and with any successful sub-cultures in the egg or in other media. Should then later experiments confirm the results obtained in the preliminary experiments that I have described, it is possible that we may eventually be enabled to elaborate a method of specific treatment of individuals actually suffering attack by small-pox, somewhat comparable to that discovered by Behring in reference to diphtheria. Should this forecast be justified in the event some such method would form a fitting complement to the process of preventive vaccination which now for well-nigh a century has stood the test of time and experience.

Dr. HAUGHTON made some remarks concerning the *rôle* which insanitary conditions play in the production of variola, and expressed his belief that similar phenomena to those of vaccinia might probably be produced by the inoculation of matter from the white swelling of a knee-joint or any other scrofulous disease.

Dr. DENHAM (Dublin) had noticed in his experiments that the vaccine from a calf approaching puberty was not nearly so efficacious as that taken from a younger calf. He agreed that the mixing of lymph with glycerine and storing for some time led to the total destruction in it of saprophytic organisms.

Mr. RENNER, Dr. DRYSDALE, and Dr. STANLEY KENT also joined in the discussion.

Dr. COPEMAN, in reply, stated that vaccine points are bad, and that if used at all they should be made of celluloid, which can be sterilised, rather than ivory, which cannot be so satisfactorily sterilised owing to the interstices in it. In answer to a question, he stated that he did not believe that the psorosperms produced in the rabbit's cornea after inoculation had anything to do with the production of small-pox, and denied that they had ever been found in vaccine lymph itself.

OPHTHALMOLOGY.

THURSDAY, AUG. 1ST.

Pseudo-Malignant Tumours of the Orbit.

Professor PANAS of Paris read a paper on this subject. He referred to a number of observations on exorbitis with tumour supposed to be malignant, but which subsided under medical treatment or an intercurrent attack of erysipelas, and which were subsequently put down as syphilitic, referring in support of this statement to a large number of Continental writers, whereas he held that a number of neoplasms thought to be lymphomas, sarcomas, or syphilomas ought to be attributed to the dyscrasia produced by some toxines. In illustration he quoted the case of a man aged thirty-five years, who presented double exophthalmos simulating in all respects sarcoma, which was completely cured by the use of arseniate of soda. The patient was free from syphilis, and the condition had been aggravated by iodide of potassium. The condition, in Professor Panas' opinion, was due to microbic infection of the cellular tissue extending from ozæna affecting the nasal fossa, the swelling being most marked on the inner side of each orbit. In another case, that of a young woman, also free from syphilis, exophthalmos of the left eye was associated with polypi of the left nostril, supposed at first to be sarcomatous. Many other cases were cited, nearly half being bilateral, and all of which subsided under treatment by arsenic or other drugs after being regarded as malignant. Experiments upon dogs by Professor Delbet were afterwards related, in which lymphadenoma was transferred to them, a specific bacillus being separated and introduced and being afterwards found in the glandular enlargements of the animals. Another set of cases was also noted in which the lacrymal glands were the primary seat, the condition being usually associated with specific febrile or venereal disease. In conclusion, Professor Panas recommended that in all such cases search should be made for the source of infection, and treatment by drugs resorted to before surgical interference was tried.

On the Diagnosis of Orbital Tumours.

Dr. H. R. SWANZY (Dublin) opened a discussion on this subject. He said there were three main questions. 1. Was a tumour of the orbit present? 2. Was it confined to the orbit? 3. Of what nature was the new growth? It was in the early stages that most difficulty arose, and the earliest sign was commonly proptosis, mostly in a somewhat oblique direction, except in tumours developing in the apex of the orbit. The development, too, was gradual and mostly unilateral. Further evidence might be obtained by palpation, which, besides confirming the presence of a tumour, might elicit information as to position and attachment. Disturbance of vision—another important sign—occurred mostly in rapidly developing tumours, in those directly affecting the optic nerve, or in the later stages of other forms. Pain or loss of motion was present with less frequency. Many cases of orbital tumour were instances of the invasion of that cavity by growths originating in the neighbouring bony sinuses, either frontal or lacrymal; the commonest were mucocele or osteomata, and the displacement of the globe was commonly downward and outward. An examination of the neighbouring fossæ, especially the nose and pharynx, was essential, as was also careful examination for cerebral symptoms and the condition of the fields of vision. Fixation and pain occurring early were to be regarded as signs of malignancy. Pulsation and bruit or thrill indicated vascular developments, and congenital tumours were mostly encephaloceles or dermoids, though the latter seldom became prominent until puberty. The consistence and site of the growth were also important elements in diagnosis, but in the great majority of cases no certain opinion could be arrived at until an operation was undertaken.

Mr. HENRY POWER referred to a case in which proptosis had disappeared on the removal of a necrosed inferior turbinated bone.

Professor FUCHS quoted a case of rhino-scleroma of both orbits which were invaded at their apex from the nasal cavities, and in which immobility of the eye occurred when the proptosis was still slight.

Dr. ARGYLL ROBERTSON corroborated the views held by Professor Panas as to the subsidence of what appeared to be organic tumour of the orbit. He recalled several such cases and narrated one in a young man in which the temporal and malar regions and brain appeared to be involved, but which completely recovered under large doses of iodide of potassium.

Mr. NETTLESHIP mentioned a case of Unilateral Stationary Proptosis with swelling in the corresponding temporal fossa and cheek in a woman between thirty and forty years of age, in whom the condition had existed for five years.

Mr. SPENCER WATSON related a case in which double proptosis and cardiac symptoms had subsided after removal of inferior turbinal and nasal growths.

Mr. ADAMS FROST referred to a case he had shown to the Ophthalmological Society which was regarded as sarcoma, and in which he had removed the large lacrymal gland on one side, finding what appeared to be a small, round-celled sarcoma. The other tumour had subsequently disappeared under iodide of potassium.

Dr. HILL GRIFFITH mentioned a case of Orbital Sarcoma in which there was an unusual amount of inflammatory action, the growth extending all round the cornea.

The Radical Operative Treatment of Trichiasis.

Dr. KENNETH SCOTT described the process as follows. An incision is firmly made on the conjunctival surface of the lid parallel to and 2 mm. from the ciliary margin dividing the tarsus completely. The eyelid is replaced in position and its divided margin grasped in forceps and forcibly everted by

Digitized by Google

carrying the handle up till it touches the brow. One needle carrying eighteen inches of silver wire is passed vertically down from the brow through the skin surface of the centre of the lid into the substance of the upper part of the tarsus, emerging at its divided edge; it then enters the original anterior surface of the lower separate portion of the tarsus, to be finally brought out on the free margin of the lid, midway between the lashes and conjunctival edge. Two other sutures are similarly introduced, one towards each end of the eyelid. The opposing ends of these three sutures, which should be left long, are now separately twisted together, not so tightly as to cause constriction, but sufficiently so to maintain the lid in its everted position. The remainder of the suture is now passed along in the tissue of the eyebrow from one extremity to the centre, at which points the corresponding twisted strands of wire are attached to it; the needle is reintroduced at the centre of the eyebrow, close to its point of emergence, and is brought out at its opposite end, where the third remaining twisted suture is secured to it. When the lower lid is the site of operation the cheek is used as a fixation point instead of the eyebrow. The operation occupies about three minutes.

A Note on the Surgical Treatment of Dislocation of the Crystalline Lens into the Anterior Chamber.

Dr. GEORGE MACKAY asked the experience of his colleagues as to what proportion of cases received permanent benefit from reduction of the dislocation, and in inviting discussion on the best method of operating for the removal of the lens in its capsule, gave his own experience in favour of the employment of a needle to fix and remove the lens from the path of the knife while making the corneal section and to prevent its falling back into the vitreous while a vectis or scoop was being passed behind it.

Mr. PRIESTLEY SMITH said that in cases of partial dislocation with high tension it was well to slacken the eye by a scleral puncture, and only to remove the lens after the tension was reduced.

Brigade-Surgeon-Lieutenant-Colonel DRAKE-BROCKMAN, Mr. GEORGE WALKER, and Dr. EMRYS JONES narrated cases of congenital or traumatic dislocation in which discission or removal of the lens had been effected.

Latent Hypermetropia in the Visual Examinations of Candidates for the Public Services.

Mr. BEAUMONT in this paper pleaded for more definite regulations with regard to the question of latent hypermetropia in the visual examination of candidates for the public services. In the Royal Navy especially he stated that, although the rule was that emmetropes alone were admissible, yet no means were adopted for the detection of hypermetropia. As a consequence it happened that hypermetropic candidates, although warned of ineligibility, often passed with flying colours, and the surgeon giving an adverse opinion was discredited.

Dr. RISIEN RUSSELL gave a limelight demonstration of experiments on the visual centres. Excitation of the frontal eye area caused movement of both eyes to the opposite side, and destruction brought about subsequent deviation to the same side. On section of the appropriate recti, excitation of particular spots elicited each separate movement of the eyes. Further experiments under absinthe showed that the cortical centre only initiated impulse, the motor force being supplied by lower centres. Ablation of one hemisphere of the cerebellum caused paresis of limbs on the same and deviation of the eyes to the opposite side.

Mr. ADAMS FROST gave an interesting limelight demonstration of various aspects of the fundus in health and disease.

Dr. MACNAUGHTON JONES read a paper on the Importance of Detection of Errors of Refraction in Neurasthenic Women, giving numerous instances of relief after correction.

FRIDAY, AUG. 2ND.

Operation in Chronic Glaucoma.

The debate on this subject was opened by Mr. Nettleship. Many cases, he said, were dependent on mental worry or grief were of a purely temporary kind, and were relieved by change of occupation, lapse of time, and general or local remedies, such as eserine. Sclero-puncture, though very effectual in acute, was practically useless in chronic glaucoma. Endeavour should be made to discriminate between different forms of chronic glaucoma, for they were not all alike. One variety associated with disorder of the menstrual functions was not relieved by iridectomy.

Mr. CRITCHETT expressed regret that the treatment of chronic glaucoma was not only a twice, but a thrice told tale. He felt that in this disease it was essential to remember the well-known text, "That thou doest do quickly," and he instanced a case of chronic glaucoma recently under his care in which the disease had existed nine months in the left eye before it affected the right, and though iridectomy was performed in both eyes the tension returned in the left. He laid great stress on the advantage of a cystoid cicatrix, saying that any ophthalmologist who could invent a certain method of securing this condition would have deserved well of his country; and he quoted a case of double chronic glaucoma at St. Mary's Hospital where he had operated on both eyes. The tension had returned in one eye, but had not done so in the other, which was protected by a cystoid cicatrix.

Mr. PRIESTLEY SMITH said that in his view the criterion of glaucoma was the presence of excess of pressure-producing symptoms. A minority only of cases exhibited cupping of the disc and narrowing of the field. The diagnosis was rendered more difficult by the existence of cases in which tension varied from time to time or in which it was insufficient to be detected by the finger. He recommended the use of the tonometer in these. He advised operation whenever there was vision worth saving, even to the bare perception of light, if the health of the patient permitted. He should be warned that the result was not certain, but that operation offered the only chance of saving what remained. The immediate danger to be feared from the operation was injury or displacement of the lens or deep-seated hæmorrhage. This risk was diminished by puncture of the sclerotic, so as to slacken the eye and so gain time, while such conditions as sleeplessness, constipation, and worry which predisposed to hæmorrhage might be relieved. Ultimate success depended on the formation of a permanent fistula so as to maintain drainage, but was also assisted by attendance to the general health so as to obviate further degenerative changes in the optic nerve.

Dr. SWANZY emphasised the advisability of early operation. There was immediate danger of deterioration of sight, but this could be better borne in the early than in the late stages; indeed, when sight was reduced to the fixing point he would refuse to operate for fear of this last remnant failing in consequence. On the other hand, there was difficulty in getting patients with only slight loss of vision in the early stage to submit to operation.

Mr. LITTLE advocated operation in the premonitory stage. When relief was not secured it was often because the incision was too near the cornea.

Mr. ADAMS FROST said it was remarkable that more astigmatism resulted from an iridectomy in glaucoma than in cataract extraction. He avoided operation as much as possible, giving cocaine and eserine every night, and performing iridectomy only when this failed.

Mr. JULER concurred with what Mr. Nettleship had said.

Mr. LEE also spoke.

Mr. MACKINLAY considered it most important to operate early and to make the incision as far back as possible. He preferred a Graefe's knife. The late Sir William Bowman pointed out the fact that an operation often backened the vision as he called it, and it was well to point this out to patients beforehand, impressing the fact that without it they would drift into blindness.

Mr. RICHARD WILLIAMS agreed with what Mr. Nettleship had said, except as to his preference for iridectomy. He had had an excellent result from sclerotomy, the operation being also free from danger.

Mr. TREACHER COLLINS explained the formation of a cystoid cicatrix by the protrusion of a knuckle of iris between the edges of the scleral wound. This was thinned and forced outward by the tension of the eye till it allowed of free filtration. In such cases a boggy condition of the conjunctival tissue around the scar was noticed.

Mr. MCHARDY approved of performing sclerotomy in the coloboma of an iridectomy when further interference was called for. He quoted Bowman in support of the opinion that postponement led to disaster. After operation he did not permit the eye to be used for six months. The incision, commenced in the usual position, should be carried far back at the apex, so as to pass rather behind the sclero-corneal junction. He thought a cystic cicatrix was associated with pricking the iris on inserting the knife. A favourable result was assisted by low diet after the

Digitized by Google

operation and an avoidance of constant padding of the eye, skilled support by the hand being substituted for the bandage at intervals.

Professor FUCHS said he had performed sclerotomy only in cases which presented increase of tension after an iridectomy. He had given up operation in cases of chronic glaucoma when there was no increase of tension to be stated; these might, however, be regarded as instances of atrophy of the disc with cupping and not as chronic glaucoma.

Dr. MEYER made a similar reservation to Professor Fuchs with regard to cases presenting only cupping of the disc. He would advise operation in chronic glaucoma under any conditions of vision short of complete extinction, preferring iridectomy to sclerotomy.

Dr. GAZET considered sclerotomy as an operation performed rather for the satisfaction of the surgeon than the interest of the patient. He preferred iridectomy, or in those cases where this was inadmissible puncture of the sclerotic near the equator of the eye.

Professor FUCHS read a paper on Erythropsia—transitory red vision—following protracted exposure of the eyes to strong light. The instances he quoted followed a walk in the snow on which the sun was shining. The phenomenon was more easily produced in some individuals than others, possibly owing to the amount of pigment present in the fundus. The fixation point was not affected, but the depth of colour increased towards the periphery of the field.

Brigade-Surgeon-Lieutenant-Colonel DRAKE-BROCKMAN said a similar condition was common after exposure to sun glare on the plains in India, especially in the subjects of cataract extraction.

Mr. BICKERTON read a paper on the Utter Neglect of the Eyesight Question in Board of Trade Official Inquiries into Shipping Disasters.

In connexion with this the following resolution was proposed by Dr. FARQUHARSON and seconded by Mr. MCHARDY: "That effect should be given by the Board of Trade to the recommendations contained in the report of the Committee of the Royal Society on Colour Vision." This was carried unanimously.

Dr. EDRIDGE GREEN described Systems of Tests for Colour Blindness, stating that many colour-blind people were able to pass a satisfactory test with Holmgren's wools.

DISEASES OF CHILDREN.

The Treatment of Hernia in Children.

Mr. RUSHTON PARKER, Professor of Surgery in University College, Liverpool, and Surgeon to the Royal Infirmary, Liverpool, introduced a discussion upon this subject. The treatment of hernia in children must obviously be either by truss or by operation. He said it is assumed that when a hernia can be kept up with a truss there is no need for further surgical interference. This maxim, generally applicable to the adult, has been thought to be specially adapted to children, in whom the permanent disappearance of hernia after the use of a truss is said to be attainable in a large proportion of cases. Mr. Parker said he would not attempt either to deny or to affirm this, as he has been chiefly consulted on behalf of children, in cases where operation was already regarded as expedient and desired by the medical attendant and friends if acceded to by him. Of the separate motive for operation in each case he had no systematic record, and was therefore unable to say in what proportion of his cases a truss might have been attempted without success, or in how many the operation was asked for to save the trouble, time, and possible failure involved in the use of a truss. The only operation applicable to all herniæ alike, strangulated or not, reducible or not, is herniotomy, with special treatment of the sac; and it was to the operative treatment of hernia in children that his paper was mainly devoted. Mr. Parker's cases had been forty in number, all inguinal, some double, and all in males except one, occurring in thirty-three persons, whose ages varied from four weeks to twelve years—2 were of twelve years, 8 from five to ten, 16 from one to four, and 7 under a year; 2 were of nine months, 1 each of seven, six, and four months, 1 of seven weeks, and 1 of four weeks. The chances of fatality must not be overlooked, and in his forty cases he had met with 3 deaths—2 from peritonitis after ten days, and so traceable to the wound; and 1 from bronchitis within twenty-four hours, an intercurrent accident. The risks of failure appeared to be now not very appreciable, but two of his earlier cases, large herniæ unfitted for a truss, recurred some months after operation. Excluding the 2 failures, 3 deaths, and 1 lost sight of, the relatives of the remaining 27 patients have been recently communicated with, and replies received from 25 announcing that in not a single case had hernia reappeared so far. Two patients had died of other disease, being free from hernia two years after operation, while 23 were reported free from all sign of hernia in June, 1895. The longest interval since operation is eleven years, but in 5 cases it is under a year, with graduated intervals between the limits. The variety of operation preferred by Mr. Parker is Macewen's, described with illustrations in the *British Medical Journal* of Dec. 10th, 1887. The material used for the deep attachment of the sac to the abdominal wall, and for the pillars of the ring when they are dealt with, is the green catgut supplied to surgeons, while that for the skin wound is usually the more readily absorbed yellow catgut. Ligature of the sac with yellow catgut was done in the two cases that failed, and also with green catgut in a few of the successful cases, but has been seldom relied on by Mr. Parker in late years. The conclusions arrived at are: (1) the operation of herniotomy, with special treatment of the sac, is adapted for the radical cure of hernia, strangulated or not, in suitably selected cases at any age; (2) the results of operation during early childhood, and even in infancy, show that at these periods of life the success obtained is probably the greatest of all, while the slight danger is not increased; and (3) there is room for choice in the details, but Mr. Parker preferred Macewen's treatment of the sac in femoral and inguinal herniotomy.

The paper was discussed by Mr. LOCKWOOD, Mr. LANGTON, Mr. MACEWEN, Dr. WARD COUSINS, Mr. MACREADY, Mr. SOUTHAM, Mr. H. P. SYMONDS, Mr. R. H. LUCY, Mr. DAMER HARRISSON, and Mr. WATERHOUSE. There was a general concensus of opinion that Macewen's operation was in the end most satisfactory, and each speaker had his own favourite method for getting over the difficulties of the operation in young children. There was also general agreement that the efficient treatment of hernia in young children by trusses among hospital out-patients was practically impossible.

FRIDAY, AUG. 2ND.

Dosage for Children.

Mr. KINGSTON BARTON opened a discussion on the Doses Suitable for Children at the Several Ages. He reviewed about forty of the preparations most employed, and discussed the dose which he found most efficacious for various purpose. He urged the desirability of inserting in the British Pharmacopœia some guide as to the doses most suitable for children, such as appears in the official Pharmacopœia for Switzerland. He did not think that the dose could be calculated from the body weight, as he considered that children required larger proportional doses than adults, and required them to be given more frequently.

Dr. D. J. LEECH considered that with the exception of stimulants, depressants, and narcotics children took drugs with less disturbance than adults. Dr. FOXWELL, Dr. DAWSON WILLIAMS, and Dr. TIBARD also referred to the remarkable tolerance of young children for some powerful drugs such as mercury, belladonna, and arsenic.

Among the papers which were read in this Section was one by Dr. ARCHIBALD GARROD and Dr. MORLEY FLETCHER on the Maternal Factors in the Causation of Rickets. They showed that in many cases improper feeding was insufficient to account for the occurrence of rickets, but that circumstances affecting the health of the mother before the birth of the child or subsequently, impairing the quality of the breast milk, must be kept in mind. Dr. JOHN THOMSON read a paper on Congenital Hypertrophy of the Pylorus and Stomach Wall; and Dr. COURLEY of Paris contributed a paper on the Non-Pathogenic Streptococci and Staphylococci of the Throat of Children.

PHARMACOLOGY.

WEDNESDAY, JULY 31ST.

Serum Therapeutics.

Dr. KLEIN opened a discussion on Serum-therapeutics by referring to the work of Behring, Kitasato, and Roux, and to the overwhelmingly favourable results of the antitoxin treatment of diphtheria which had been published. He, however, would only deal with the scientific aspects of the question. Experimentally, the effects and value of the antitoxin serum

Digitized by Google

were so striking and could be so easily tested that it would be strange if a similar beneficial effect were not manifested when it was used upon the human subject. Immunity was of different kinds; there was natural immunity when the individual was insusceptible to a particular infective disease, acquired immunity when a first attack of a disease protected against subsequent attacks, and artificial immunity when the insusceptibility was the result of certain treatment. Natural immunity was altogether different from acquired immunity, the former being probably dependent upon some peculiarity of cells or tissues, which he would not enter into; the latter to the presence of chemical substances in the blood, which were termed anti-bodies. The methods of producing immunity to diphtheria and the production of antitoxin by injection of gradually increasing doses of the toxins or of the toxins *plus* living bacilli were then briefly described. The antitoxins had a very great power of neutralising the toxins, but much larger doses had to be employed if living bacilli were present in addition. Hence the antitoxic substance and the substance immunising against the living bacilli seemed to be distinct, and, in fact, it could be shown experimentally that they were not formed simultaneously or to the same degree. The antitoxic substance was perhaps a ferment, and in the future two classes of animals might be kept, one class immunised against the toxins, and furnishing antitoxin for the treatment of diphtheria, another class immunised against the living bacilli, and furnishing a serum which might be used for preventive inoculation. Experimentally, the value of antitoxin was as firmly established as that of any known drug.

Dr. WASHBOURN said that serum therapeutics marked an epoch in medical treatment comparable to the introduction of antiseptics into surgical practice. Whereas by the introduction of antiseptics the field of surgery had been vastly extended, medicine, except for the improvements in diagnosis, had remained almost stationary. The progress of bacterial therapeutics had been slow, and when tuberculin was found to be a failure, for a time a death blow seemed to have been given to this branch of treatment. The disfavour with which the antitoxin treatment had been received by some was due partly to preconceived ideas, based on the failure of the tuberculin treatment. The cases of tuberculin and antitoxin, however, rested upon a very different foundation, for the latter had been thoroughly tested experimentally before being published. With regard to tetanus antitoxin, as pointed out by Dr. Kanthack, the results seemed to be somewhat disappointing, but there was the disadvantage that only a comparatively few cases had been treated, and no observer had had a series of cases. There were two methods by which the value of diphtheria antitoxin could be gauged—the clinical and the statistical; and a large number of cases and series of cases were now available for criticism. As regards the statistical method, it was most important that the age of the patients should be mentioned, for whereas for children under five years the mortality was 49·09 per cent., for persons over fifteen years the mortality was only 4·6 per cent. The varying severity of different epidemics was a factor which could not be neglected, but by taking a large number of cases in many series this fallacy could be eliminated. The position of the membrane, whether faucial only or involving the larynx, was another important factor. Many of the published records of isolated or small series of cases were of little value, especially if the ages were not stated. Over 3000 cases treated with antitoxin were now available for analysis, and statistics showed a diminished mortality, in some instances one-half that which existed in pre-antitoxin days. This was the case in Paris, where at the same time at the Trousseau Hospital under the old treatment the mortality remained up to the average, and also in Berlin, where there was a great diminution of mortality when the antitoxin was used, a rise when the supply of the remedy failed, followed at once by a decline on the resumption of the use of the remedy. Statistics, therefore, definitely proved the advantage of the antitoxin treatment. Clinically the following features were observed under the antitoxin treatment. The exudation clears off more rapidly, and so in many cases dispenses with the necessity for tracheotomy. The temperature, which, however, is not of great importance in diphtheria, when high is lowered, the pulse becomes slower and more regular, although no direct action is observable on the heart. No deleterious effects, such as nephritis and anuria, could be ascribed to the remedy. As regards the occurrence of post-diphtheritic paralysis more extended observations were required. Where the antitoxin failed it was frequently due to invasion of the membrane by septic bacteria, streptococci, and the like, whereby a septicæmic condition might be produced. Slight complications, such as rashes, pyrexia, and joint pains, sometimes attended the use of the remedy, but these were of a transient character and only retarded recovery somewhat. The rashes were of an erythematous or urticarial nature, and the joint pains proceeded usually from the structures around the joint, although actual effusion might occur. Dr. Washbourn emphasised the importance of antiseptic precautions for the injecting and the necessity for regulating the dose according to the age of the patient and the severity of the disease. As regards the prophylactic use of the serum, the protection did not last long, and it would only be exceptionally indicated. In conclusion, the possibilities of serum therapeutics were touched upon as applied to bacterial diseases such as erysipelas, pneumonia, puerperal fever, and the like.

Professor CHARTERIS (Glasgow) spoke of the cases of diphtheria he had seen treated with antitoxin. There could be no doubt about its efficacy; the membrane ceased to spread, the pulse became fuller and stronger, and the whole aspect of the patient improved. With regard to the ill-effects attributed to the use of antitoxin, he had made experiments on animals with the preparations supplied by Aronson, Behring, Burroughs and Wellcome, and the British Institute of Preventive Medicine, and in no case was any deleterious action observed.

Dr. R. T. HEWLETT said that he wished to say a few words with regard to tetanus antitoxin. After a brief description of its mode of preparation the speaker referred to the mortality from tetanus, and from a consideration of the statistics concluded that this was about 75 per cent. for all cases. He had collected details of sixty-one cases of tetanus treated with antitoxin with twenty-two deaths, giving a mortality of but 36 per cent. This, however, was probably too favourable, and it would seem that the acute cases were little benefited, but in the chronic ones the tetanus antitoxin distinctly increased the chances of cure. A recent report from one of the West Indian islands was encouraging, for the Acting Surgeon-General reported that the treatment of tetanus by antitoxin had been so satisfactory that he recommended that a further supply of the remedy be obtained at once. The speaker concluded that it was our duty to employ the antitoxin in all cases of tetanus, and emphasised the importance of early treatment. The use of tetanus antitoxin as an immunising agent was most promising, especially in certain tropical countries where tetanus was of frequent occurrence.

Dr. TIRARD had treated with antitoxin sixteen cases of diphtheria at the Evelina Hospital with only two deaths, a considerable reduction compared with the previous rate of mortality, and one of these was due to hæmorrhage from the tonsillar artery. The effects of the treatment were very striking from the first—the membrane "went," there was marked improvement in the general condition, the pulse increased in force and diminished in rapidity, and the temperature fell or, at any rate, did not rise. All the cases had been carefully watched, and no paralytic symptoms had occurred. Altogether the results of the treatment were most encouraging, but it must still be regarded as being on its trial.

Dr. GAYTON was not favourably impressed with the antitoxin treatment of diphtheria. He believed that cases which would have died under the old treatment died under the new, while paralysis became more frequent and the liability to nephritis was increased by antitoxin. It was true that there was a slightly lessened mortality (about 5 per cent.) under the use of antitoxin, but this was to be attributed to an alteration in the character of the cases. The rashes &c. attending the use of antitoxin were not of such slight importance as had been stated. Finally, for those experienced in the clinical diagnosis of diphtheria the bacteriological diagnosis was unnecessary and often misleading.

Dr. CAIGER had treated 230 cases of diphtheria with antitoxin. Cardiac failure had been reduced, but paralytic sequelæ were more frequent. This was to be attributed to the fact that a larger proportion of severe cases recovered than formerly. The duration of the membrane, which before the use of antitoxin was 4·6 days, was reduced to 2·6 days. In the nasal form the acrid discharge was soon checked and the patients rendered more comfortable. In laryngeal cases the benefits were most marked; both the membrane and swelling soon disappeared, and the number of cases requiring tracheotomy was reduced from 70 per cent. to 43 per cent.

Digitized by Google

The mortality was lessened, and even in the fatal cases life was prolonged to 7·2 days, whereas it was previously only 4·3 days. After commenting on the character of the rashes, Dr. Caiger referred to the dose of antitoxin, and said he had given much larger amounts than were recommended, starting with 50 c.c. and administering 160-180 c.c. during the first three days, and he considered the results were much better.

Professor FRASER (Edinburgh) commented on the method usually employed to test antitoxin, and considered that the small amount of antitoxin required to neutralise the minimum fatal dose of toxin, when administered previously or simultaneously, was calculated to give an exaggerated idea of its potency. He advocated the standardising of antitoxin by injecting it at some given time after the dose of toxine.

Mr. BOKENHAM referred to the large bulk of fluid which had to be injected and to the convenience of a more concentrated form of the antitoxin. When dried, the scales would dissolve in a volume of water only one-third that of the original serum. He had also succeeded in precipitating the albuminous matters in the serum more or less perfectly, thereby obtaining a concentrated product.

Dr. KLEIN, in reply, alluded to the use of dried serum, and believed that in this form the antitoxin was less likely to produce the rashes and other complications which had been mentioned. With regard to Dr. Gayton's communication he should have liked to have had more information respecting the dose administered.

Dr. WASHBOURN agreed with Professor Fraser as to the testing of antitoxin. Referring to Dr. Gayton's cases, he said their number was too small to attach great importance to them, and as it was the mortality had been reduced 5 per cent. He should have liked more information as to the dose and method of administration. He could not agree that the bacteriological diagnosis of diphtheria was of little value.

Production of Immunity to Snake-bites.

Professor FRASER (Edinburgh) then read a paper on the Production of Immunity to Snake-bites, and described the method employed. Antivenene could be produced by internal administration of the venom as well as by subcutaneous injection; the latter, however, was the better. The blood of venomous snakes was strongly antitoxic and protected not only against their own venom, but also against that of other species. The antidotal action of antivenene seemed to be rather of the nature of a chemical reaction than of a physiological antidote. With regard to the administration of antivenene, several successive doses seemed to be more effectual than one large one. Antivenene should be injected at the seat of the bite, before the ligature, if applied round the limb, had been removed and before excision; 20 c.c. sufficed for the initial dose.

Professor STOKVIS (Amsterdam) asked whether Professor Fraser had administered antivenene by epidermal application. He believed that in the West Indies the snake-catchers rub themselves with the skin of a recently killed snake before pursuing their occupation, and were supposed to be thus rendered immune.

Professor FRASER, in reply, stated that he had not tried epidermal application of antivenene, but as immunity could be produced by absorption through the epithelial lining of the stomach it was quite possible that inunction would act similarly. It was a point worthy of trial.

THURSDAY, AUG. 1ST.

Discussion on Revision of the British Pharmacopœia.

The greater part of the sitting was devoted to a consideration of the revision of the British Pharmacopœia, Dr. T. LAUDER BRUNTON presiding.

Professor LEECH (Manchester), in opening the discussion, said that he was a member of the General Medical Council, and was hoping to learn the views of practitioners on the question of revision. He suggested that the discussion might be confined to the following considerations: (1) the nature and extent of the list of remedies; (2) the preparation of compounds so far as concerned their medical use; (3) weights and measures; and (4) the amount of accessory information to be given. Much information had been gained from the memorandum of the Therapeutic Committee of the Association, and it appeared that fifty-four drugs and preparations were never used by over 5000 practitioners out of the 5609 who had sent replies. At the same time every drug was used by someone, and it was important to ascertain how this came about before deciding on omissions. As regards examinations, it was absurd to expect students to acquire a knowledge of drugs which would never be used by them. The Pharmacopœia must keep pace with the times, and the question arose as to whether the new preparations, such as tabloids, granules, &c., should be included. Should the details of the making of poultices find a place? With regard to the tests, it would be well to specify what the impurities were which the tests were intended to detect. The British Pharmacopœia was the only one in which the metric system of weights and measures was not adopted, and it would probably be found expedient to include them side by side with the English ones. As regards dosage, simplification was very desirable, and of the powerful remedies the maximum and minimum doses might be specified with advantage. Finally, it was only necessary to describe the drugs generally employed, and all doubtful matter should be excluded.

Dr. DONALD MACALISTER (Cambridge) said that the essential formulæ of the Pharmacopœia should be so arranged as to be easily remembered, and so that the superfluous should be best avoided. Uniformity should be aimed at. Thus as regards the tinctures, although it might not be feasible to make them of such strengths that the dose should be uniform, it would be possible to have two or three classes, so that all the tinctures in a class should have the same dose. As the active constituents in roots, leaves, &c., varied considerably under different conditions it would be desirable to add directions for standardising the extracts and tinctures. Two strengths of the same preparation—as the liquor ammoniæ acetatis and the liquor ammoniæ acetatis fortior—were confusing and might lead to dangerous errors. The metric system should be introduced, and a concise table of solubilities would be most useful. As regards enemata, formulæ for some simple enemata might be retained, but the amount of the active constituent to be introduced should be left to the prescriber.

Professor BRADBURY (Cambridge) considered that the Pharmacopœia contained much useless matter—for instance, the mode of preparation of chloroform, ammonia, &c. Purely pharmacological methods only should be retained, as the preparation of infusions and tinctures. Many improvements might be made in the various menstrua and in the bases for the unguenta. Uniformity of dose was a subject of the greatest importance. In the present Pharmacopœia some of the doses were too large, as those of tincture of aconite and dilute hydrocyanic acid; the latter might preferably be prepared as a 1 per cent. solution instead of a 2 per cent. In other cases the doses were too small, as the liquid extracts of ergot and male fern and the subnitrate and carbonate of bismuth, of which the dose might be up to one drachm. It would also be very valuable to give the maximum amount which could be administered with safety in the twenty-four hours, especially when the drug tended to be cumulative. The metric system should be introduced for the purpose of preparation, for prescribing its use might be optional, while the Centigrade scale should replace the Fahrenheit.

Mr. MAHOMED thought that the number of preparations of several drugs might be reduced with advantage. He strongly urged the desirability of uniformity in dosage wherever this was practicable.

Dr. T. JONES considered that medicated bougies and pessaries might be introduced with advantage, and that the present selection of suppositories was not a good one, while the doses of drugs to be administered by the rectum needed careful revision.

Dr. TIRARD spoke of the numerous suggestions he had received as secretary of the Therapeutic Committee of the Association in the course of an investigation of the relative frequency of employment of certain drugs. Many of the suggestions were valuable and had already fallen from previous speakers. He thought too much had been made of the Pharmacopœia belonging wholly to medical men or wholly to chemists; it was a standard of purity for the use of both. Mr. NEVILLE WOOD, Dr. MAYBURY, Dr. FRASER, and Dr. STOCKMAN also took part in the discussion, the last suggesting that the Therapeutic Committee might begin working not for the next Pharmacopœia but for the one "after next." Much of the ground covered by the various speakers closely followed the various criticisms of the Pharmacopœia which have appeared in these columns and in other journals.

Professor CHARTERIS (Glasgow) said that the doses and the tests for impurities in the present Pharmacopœia were in many cases incorrect. The introduction of the metric system of weights and measures was also desirable.

Digitized by Google

The discussion was continued by Dr. CARTER, Professor FRASER, Professor RALPH STOCKMAN, and others, and Professor LEECH briefly replied.

In the short time that remained at the end of the discussion, papers, among others, were read by Dr. SURVEYOR and Dr. VAUGHAN HARLEY on the Action of β-Naphthol and Bismuth Subnitrate as Intestinal Antiseptics, and by Dr. C. D. F. PHILLIPS on the Pharmacological Action of Berberine.

ETHICS.

THURSDAY, AUG. 1ST.

Clubs, Medical Aid Societies, and Contract Practice.

On Thursday morning a debate on this subject was opened by Mr. DOYNE. He spoke as to the inability of the General Medical Council to interfere, and the necessity of establishing between the profession and the public an arrangement dealing with the commercial aspect of the case. He thought the British Medical Association could, and ought to, take the lead, and might, if it chose, settle the difficulty. The commercial sense of the country would not ignore that there was a rightful claim for at least a minimum rate of remuneration. This minimum he thought might be fixed at 2*d*. per week per individual and 2*d*. extra for each visit at home. Medical charities that could not pay that rate should be reorganised on a better basis, and the Poor-law might also be called upon to pay this contract minimum rate. In a word, he demanded for the medical profession a living wage.

Dr. FREDERICK PEARSE likewise protested against the "sweating" of the profession. He said that most societies made their members pay 2*s*. to 4*s*. per member per annum, and he calculated that there was on an average one week's illness per member, necessitating three consultations, and each should be paid at the rate of 2*s*. 6*d*. Thus, 7*s*. 6*d*. per annum per member was something like a fair rate for contract work. Many friendly societies now wanted to give benefits to children under three years old. This caused a great increase of work. Further, there were female lodges, and women were accepted on the same terms as healthy males, though they required much more attention. Undoubtedly the growth of clubs and aid associations injured medical practice all over the country. The tendency of the age was to develop in all directions the spirit of association, and the grievance would become universal if energetic measures were not taken. In Portsmouth, fortunately, the medical profession had united. They felt they must combine, or they would become the slaves of other combinations. Dr. Pearse distributed among the Section a written formula of the pledge taken by the members of the Portsmouth Medical Union. It was worded as follows:—"We, the undersigned medical practitioners, practising in Portsmouth and the neighbourhood, hereby pledge one another that we will not take the office of medical officer to any friendly society vacated by the discharge or resignation of any medical practitioner in the district on account of his refusal to accept any additional burden or new conditions of his duties as medical officer."

Dr. W. R. RICH spoke energetically against those who gave gratuitous services to so-called charitable institutions, and qualified them as "traitors" to their profession. Voluntary hospitals were also often "a public scandal." The out-patient department was managed in a shameful manner. He knew of a dispensary where as many as a thousand bottles of medicine had been given out in a day. This was not serious medical treatment, and by crowding so many sick together the dispensary in question had been rightly qualified as a centre for the spread of disease. Yet this institution prides itself in being a model among such organisations. The profession must combine. It must check this system, which, by creating monopolies, engendered tyranny. The commercial evolution of to-day was disintegrating the medical profession. Medical men were flooding the market, and monopolists profited by this glut to convert medical men into wage slaves. A medical man was also employed as a lever to ensure the success of some general insurance business. He was a tool in the hands of a society. If he refused to lend himself to this he was called bad names, and described as a man who had no feeling for the suffering of the poor. However, at Coventry they had succeeded in getting six medical men to resign their positions on these societies. If the societies imported a foreigner, this was better than to have reputable men doing disreputable work. One difficulty was the fact that medical men were not, as a rule, good business men. They had founded, however, at Coventry a Public Medical Service Society, and eleven of the local practitioners had joined this movement. Their Society had for purpose to keep medical service under the control of medical men. They had now about 6000 members subscribing to their society, but no one was allowed to subscribe who earned more than £2 a week. They had further succeeded in checking the odious system of underselling by which medical men waged war against each other, and they now contemplated attacking the hospitals, which too often were merely places for "the evacuation of medical refuse," a remark which was greeted with laughter and cheers. The Section was equally pleased when Dr. Rice described the efforts of the medical profession as a whole to deal with the question before them that day as "nebulous, amorphous, anæmic, and uncertain."

Dr. HEMMING complained of the absence from the Section of young men; this was the more unfortunate as they were the most concerned in the question. He spoke of the antiquity of sick benefit funds, mentioning one society which was founded in 1750 and which had been recently killed by the reforming parson of the parish. But what was club practice about fifty years ago? The "very name stank," and clubmen were treated shamefully. He urged that it was first necessary to treat such patients well. By that means the profession would gain the public confidence and sympathy, and then their claims would meet with a more ready acceptance. Men who paid from 4*s*. to 7*s*. annually conceived that they had a right to be properly attended; and he thought that in the present day the medicine and care given were fairly good. He did not find it difficult to do contract work; indeed, it was easier than private practice among the same class of patients. Workmen were quite determined to manage their own affairs; it was only necessary to educate them ethically as well as they had been educated politically. He thought that where operations had to be performed an extra rate should be paid; and he believed that most working class organisations would make an extra allowance if the proposal were put to them straight as a question from man to man, of fair play between the working practitioner and the working artisan. On the other hand he was bitterly opposed to what were known as medical aid associations. In Devonshire they had begun to float such associations, but the medical men had written to one another and had managed to get rid of them.

Mr. GOSS, who followed, declared that club practice appeared better the further one got away from it. Elderly practitioners who no longer needed such work could best afford to talk about duty to the poor. Some good remedies had been suggested by the various speakers. Of course, organisation was the first of necessities; then mutual local pledges such as that taken by the practitioners at Portsmouth were likely to be very effective. He thought that as the State benefited by large families the State should aid such instead of leaving them to the charity of medical men. The latter, if they accepted contract work, should do it well, acquire a reputation for good work, and then claim a higher scale of remuneration.

Dr. ELLISTON, as surgeon to a country hospital, stated that they did their best to eliminate patients who could pay. Sick benefits were really a mathematical question. He believed they were unanimous in saying that private clubs and medical aid societies should be abolished. (Loud applause.) A county medical club, to which he belonged, excluded men who earned more than £1 a week or servants with more than £8 a year. The fee was 5*s*. for a man, 5*s*. for his wife, and a shilling each for children, up to the maximum of 15*s*. Of this, 1*s*. was deducted for managing expenses; and, as he had no trouble in collecting the money, he found this worked well.

Dr. NEWMAN maintained that each member should pay annually one week's earnings, which would be from 14*s*. to £1 in rural districts; and the labourers he had questioned on the subject had all agreed that this was a fair estimate. He urged that medical men in the service of medical aid societies should be requested to resign their membership of the British Medical Association.

Surgeon-Captain J. J. A. RAYE, who had been challenged as working for some of the accused benefit societies, protested that it was not fair to confound friendly societies with medical aid associations. He belonged to the Foresters and other similar benefit societies. They gave him a dispenser, all the drugs he required, a house to live in, and a fair

Digitized by Google

salary. He recognised that there was a grievance with regard to the admission of outside members, and against this he had always protested, notably at the dinners given by the Foresters and the Oddfellows. He had always preached the exclusion of those who were able to pay a medical man's bill, but he had no power to enforce such a rule; and on one occasion, when he was about to resign, he had ascertained that forty-two applications had been made by persons who, though holding the M.D. and the M.R.C.S. qualifications, were eager to get his post. He quite agreed to the establishment of a wage limit if it could be shown how this could be done. In answer to questions Surgeon-Captain Raye said that he did not receive the whole of the money that was paid by the members, but the society paid for his cabs, his house, his assistant, and his drugs. The secretary of the society was the only other paid official. Profits were set aside to meet years of epidemic. He had to attend to some 4000 persons. Some interruptions here occurred. One member present suggested that at a penny per week this would mean £800 a year, and asked whether as much as this was paid; while others protested that 4000 persons were more than any one man could attend. But Surgeon-Captain Raye held the meeting down to the question whether, if he resigned, they could guarantee that no one else would take his position, and this, perhaps, at even a smaller salary.

Mr. PHILIP LEE (Cork) then spoke, and related how his branch of the British Medical Association had been in the thick of the fight. They had to thank the Association for its help and sympathy. Their local branch had drawn up rules fixing the wage limit at £4 a week, which doubtless was too high. The Cork clubs had 4000 members and thirteen medical officers. If they calculated four in the family, this made a population of 16,000, and that was a very large proportion of the inhabitants of the town. Though these clubs represented every shade of religious and political opinion, and were constantly at war with each other, they united to fight the medical men, and the newspapers backed the clubs, denouncing the medical men as money-grubbers. It was galling to find that the clubs and the imported medical men were laughing at the British Medical Association as incapable of doing anything. They had subscribed among themselves £400 to fight the matter, and outside subscriptions had also been received. They were not fighting for money, but for principle, and they looked to the British Medical Association for assistance. No imported medical men should be admitted into the Association, and the members of the Association should refuse to enter into consultation with them.

Mr. GEORGE BROWN urged that the profession should form itself into union.

A Member urged that there should be a rent limit as well as a wage limit.

After some more remarks from Mr. DOYNE the debate concluded with the understanding that a resolution on the subject would be put at an ulterior meeting of the Section.

FRIDAY, AUG. 2ND.

The Section met again at King's College under the presidency of Dr. CLEVELAND; there were no set subjects for discussion, but certain resolutions were proposed.

The first resolution, proposed by the Chairman and seconded by Mr. GEORGE BROWN, was carried unanimously:—

"That the employment of unqualified assistants in visiting patients is injurious to the interests of the public as well as to those of the profession."

The second resolution was proposed by Mr. PHILIP LEE and seconded by Dr. MAJOR GREENWOOD:—

"That, in the opinion of this Section, any practitioner who wilfully violates generally received rules of professional ethics be not met in any professional intercourse whatever, save in a case of very urgent danger to an individual patient."

This was also carried unanimously.

The third resolution was proposed by Dr. G. W. POTTER and seconded by Dr. MAJOR GREENWOOD:—

"That advertising in any shape is highly derogatory to the profession, and that the Council be requested to use every effort to suppress it."

A good deal of discussion arose upon this as to who should be the deciding body to adjudicate upon the question of what does or does not constitute advertising, but eventually the resolution was agreed to.

The fourth resolution was the outcome of the discussion held on Thursday, Aug. 1st, about medical aid societies. It was moved by Dr. MAJOR GREENWOOD and seconded by Dr. J. BROWN (Bacup):—

"That the Council be requested to take steps to prevent members of the British Medical Association accepting posts in medical aid and kindred societies, and that, in the opinion of the Section, no practitioner who accepts office in any society of this kind ought to be eligible for membership of the Association; that medical aid societies be defined to be 'any lay association which endeavours to obtain pecuniary profit for its members solely out of the labour of salaried medical officers.'"

Dr. T. F. PEARSE moved and Mr. PHILIP LEE seconded:—

"That the Council be requested to open a fund to indemnify medical men in their contests against the action of friendly societies."

Dr. HENRY and Mr. BROADBENT (Manchester) moved a resolution to the effect:—

"That the Council be requested to communicate with the Universities and the medical corporations with a view to discouraging graduates from taking office under medical aid associations."

Mr. BOUSFIELD moved in a very clearly and well-put speech, and Mr. BROADBENT (Manchester) seconded, the following resolution:—

"That this meeting is unanimously of opinion that a suitable authority should have powers of control over irregular practices of the same kind as those exercised by the Incorporated Law Society and the Inns of Court, and urges the Council to approach the Government with a preference for this Association as the controlling body."

A very long resolution, proposed by Dr. MCNEE and seconded by Dr. K. SIBLEY, proposed that teachers and professors in medical schools should impress upon students and pupils the importance of *esprit de corps* and coöperation both as regards their own interests and those of their future patients.

Mr. NELSON HARDY and Dr. HUGH WOODS moved a resolution:—

"That members of the Association should not hold office in any hospital which is not really a public institution, and that members of the medical staff of hospitals having pay wards should not attend the inmates of such wards gratuitously."

The meeting terminated with a vote of thanks to the President.

CLINICO-PATHOLOGICAL MUSEUM.

[SECOND NOTICE.]

Last week we described the morbid anatomical specimens exhibited in this important collection, and it remains now to notice the bacteriological exhibits, the pictures, and the patients shown.

Compared with the bacteriological exhibition of last year at Bristol the present one is numerically inferior, but in point of originality this one takes the lead. Take, for instance, the Ringworm exhibit of Dr. Colcott Fox. Dr. Leslie Roberts read an interesting paper in the Dermatological Section on the Parasites of Ringworm, but the study of this subject has for the most part been delegated to foreign writers, especially French. It is, therefore, with much pleasure, for the honour of Great Britain, that we notice the admirable exhibit of photographs and cultures shown by Dr. Colcott Fox. This gentleman and Dr. Blaxall have examined 200 cases of ringworm and cultivated the many different organisms found in this disease, with a view to differentiate the various species. The inquiry is intricate owing to the difficulty of obtaining pure cultures, but the organisms which produce ringworm may be classified into: (1) Microsporon audouini, the common rebellious small-spored fungus found by them in 70 per cent. of the cases (as compared with 60 per cent. by French writers); and (2) tricophyton megalosporon, a large-spored fungus derived mostly from animal contagion. Of this there are a large number of different species, capable, however, of being grouped into two principal divisions—(*a*) endothrix (infiltrating the hair shaft), and (*b*) ectothrix (chiefly outside the hair, but sometimes making its way into the interior). Beautiful photo-micrographs and cultures on the various media were exhibited of these different species.

Dr. MONCKTON COPEMAN and Mr. KENT exhibited the results of their investigations into the bacteriology of vaccinia and variola. A beautifully stained microscopic specimen, labeled vaccinia, of a bacillus resembling tubercle and many other bacilli in appearance was shown, but we were informed by the exhibitor that when it is inoculated into calves it showed, after one or two removes, results indistinguishable from vaccinia as seen in that animal. When transferred to children from the calf the result is equally typical. The organism is small and stains with great difficulty, and it will not grow on ordinary culture media. The

Digitized by Google

difference or identity of this with the bacillus variolæ is still under investigation.

Dr. SIMS WOODHEAD exhibited a series of Diphtheria Cultures, showing a day's work at the laboratory of the Conjoint Board on behalf of the Metropolitan Asylums Board. Forty-one cases were examined on July 29th, and from thirty-six of these cultures of the coccus diphtheriæ were obtained on blood serum. Some of these were convalescent cases, which in pre-microbic days would have been regarded as free from infectiveness, but which, nevertheless, gave cultures showing that they were still infectious. The large number of 5143 cases have been so examined up to date. An excellent series of bacteria fixed with formic aldehyde for museum purposes are also exhibited.

Dr. MACFADYEN and Dr. HEWLETT, from the British Institute of Preventive Medicine, displayed: (1) A very complete series of cultures of chromogenic organisms, which are chiefly derived from water; (2) numerous examples of cultures of non-pathogenic saprophytic or putrefactive organisms, useful for differential purposes; (3) a set of cultures of pathogenic organisms, such as cholera, pyogenic microbes, tetanus, glanders, erysipelas, symptomatic anthrax, and actinomyces; (4) a series of thermophylic bacteria (a subject to which Dr. Macfadyen has devoted much attention)—i.e., microbes growing at a temperature of 140° to 150° F., which destroys protoplasm; these are chiefly saprophytic organisms derived from water, soil, hay, &c.; and (5) some excellent photo-micrographs of gonococcus, the bacillus of tetanus, &c., by Mr. Barnard.

Mr. JOSEPH LUNT, from the water laboratory of the same institute, exhibited a series of water-borne organisms, amongst which may specially be noted a differential series of bacillus coli communis and the typhoid fever bacillus. These organisms are extremely alike in their physical properties though so different in their lethal powers. Both grow alike in form and colour, and both produce acid from sugar-agar; but the former produces gas at the bottom of a sugar-agar tube. Cultures of typhoid fever are also shown from bacteria after living in sterilised water for seventy-six days.

Dr. KLEIN showed a fine collection of bacteriological lantern slides, chiefly useful for educational purposes; and Dr. VINCENT HARRIS a series of bacteria infecting the alimentary tract. Among the apparatus shown was the Berkefeld filtration apparatus for deriving enzymes from bacterial fluids; various accessories for photo-micrographic work; and a new instrument for the cultivation of anaerobes (Professor D. J. Hamilton).

Turning next to the pictures, which were arranged around the museum, the most complete series is a collection of thirty-seven platinotype reproductions and five coloured sketches, illustrating the various stages of the epidemic skin disease described by Dr. Savill in 1891. They show well the successive stages of this protean and interesting disorder, how that it begins with a papular or papulo-erythematous rash and passes on in the course of four or more days to extensive shedding of the cuticle. The serious and sometimes fatal nature of the malady was well depicted, but the picture of a child who had a very mild and transitory attack was also shown. Photographs of cultures and of the microbes isolated by Savill and Russell in this disease were also shown, and some excellent photo-micrographs illustrating the histology and the peculiar and pathognomonic nuclear change discovered by Echeverria also find a place. This series is lent by the Royal College of Surgeons, and forms as complete a set of pictures illustrating one disease as could well be grouped together.

The great labour involved in arranging this museum in so short a time doubtless explains why the remaining pictures were not more definitely arranged and labeled. Mr. HUTCHINSON, from his rich store of illustrations, exhibited pictures of detached epiphyses and their results (a series tallying well with the preparations we referred to last week); tuberculosis of the skin resulting from inoculation of the phthisical sputum of one lad into the arm of another whom he was tattooing; lupus and other skin affections; and diseases of the bones. Pictures of many rare and interesting conditions adorned the tables, among which may be mentioned acute dermatitis, probably the result of chloralamide; Raynaud's disease, congenital syphilis, xeroderma pigmentosa, mycosis fungoides, various drug eruptions, and the various forms of lupus. Among the coloured sketches was one labeled "An unusual form of the lichen of childhood," sketched from a patient under the care of Mr. Morrant Baker, and bearing the date of 1882. The picture bears a very striking resemblance to the papulo-pustular (acneïform) eruption upon which Dr. Colcott Fox read a paper in the Dermatological Section, and which has also been described by Crocker under the name acne scrofulosorum, and Jamieson under the name of acne varioliforme.

Dr. THOMAS H. MORTON exhibited a series of lantern slides illustrating vaccinia, variola, and other morbid conditions.

In order to complete the provision for a veritable clinico-pathological exhibition it was arranged that patients should attend at 9.30 each morning for demonstration. We can only briefly notice these, though many were of considerable interest.

Mr. HUTCHINSON exhibited—(1) a classical case of universal molluscum fibrosum, photographs of which at different stages of this slow growing disease were displayed in the Museum; (2) a case of papular eruption described as prurigo-keloid, though after inspecting the hard, glossy, lichenoid papules it seemed to some to be a pity to use the word "keloid" in this connexion; (3) urticaria pigmentosa; (4) a rare form of lupus vulgaris; (5) symmetrical paralysis of the seventh pair of nerves, probably resulting from syphilitic otitis media; (6) unilateral hydrocystoma and unilateral sweating on the right side of the face following neuralgia of the fifth nerve on the same side; (7) acrocephalus (finger-tip sloughing) which occurred suddenly in connexion with a severe illness (drawings from three other patients suffering from the same condition were placed in the Museum; the curious feature of all the cases was their being unattended by Raynaud's phenomena, and only one (an elderly person) had any discoverable arterial disease); and (8) a case of recovery from leprosy.

Mr. EDGAR WILLETT exhibited—(1) a case of varicose aneurysm of the vessels of the right arm; and (2) a case of osteitis deformans in a woman aged forty-nine, affecting only the left tibia. The illness had only lasted two years. A specimen of a case affecting one bone (the radius) was placed in the Museum.

Mr. ALFRED WILLETT exhibited a case of ligature of the innominate, subclavian, and carotid arteries for subclavian aneurysm on the right side. The operation had been done in January, 1893.

Dr. PHINEAS ABRAHAM exhibited—(1) a case of lupus verrucosus of twelve years' growth affecting the left hand, the right hand having been affected five months ago; (2) a bromide eruption resembling a pustular syphilide, which started at the site of a bite only ten months before, although the patient had taken bromide for seven years; (3) a case of pemphigus which bore a strong resemblance to dermatitis herpetiformis (Dühring); (4) a case of pityriasis rubra pilaris (Devergie) in a little girl aged seven, lasting four months, and showing now the pale brown thickening of the skin distributed like gloves on the hands and feet; and (5) a remarkable pigmented nævus of the foot, supervening on varicose veins. The same patient exhibited leucoderma on the body and alopecia of the scalp.

Dr. F. R. WALTERS exhibited an interesting case of universal hypertrophic osteo-arthropathy of pulmonary origin in a man aged thirty-four. The hands were considerably enlarged, partly from osseous hypertrophy and partly from hypertrophy of the other tissues, and the edges and ends of a great number of the bones of the skeleton were lipped. The patient was the subject of pulmonary fibrosis, bronchitis, and emphysema, and a similar connexion between pulmonary disease and osteo-arthropathy had been traced in other cases. A paper on the affection was read by the exhibitor in the Pathological Section.

Space does not permit us to describe, or even to enumerate, all the wealth of material comprised in this storehouse of clinical and pathological objects, which, owing to its position and want of announcement, was well-nigh delegated to oblivion, but which, in our opinion, was one of the most interesting and instructive departments of the meeting of the British Medical Association, partly because the kind of knowledge was objective and not speculative, and partly because by careful selection and collection it brought into view all certain knowledge of recent date and much other interesting matter.

THE MUSEUM.

I.—DRUGS (*continued from p. 313*).

To the list of new and recent remedies described in the concluding paragraph of the article under the above heading in our last issue we may add: cocainæ phenas, which, acting as a local anæsthetic, has also the advantage of being antiseptic; duboisine sulphas, obtained from Duboisia Hopwoodii, like hyoscine, has been used as a sedative and hypnotic in mental disorders; formanilid, with the same uses as antipyrine, but less dangerous; ichthyol, as a suppository in prostatitis; magnesium sulphite, in tablet form, for the treatment of diphtheria; methyl chloride in cylinders for the purpose of spraying parts affected with neuralgia; methylene blue, used in diphtheria and as an injection in cancerous growths, and administered also with benefit, it is said, in malaria; oxychinaseptol, useful as a deodoriser in foul sores and discharges; salacetol, the salicylic acid of which is set free in the intestine, is employed in choleraic diarrhœa with castor oil; salipyrin, salophen, serviceable in painful nervous disorders, acting like and related to antipyrin; trional, already employed in post-epileptic delirium, and useful also in the night sweats of phthisis; and tropococain, a local anæsthetic for the eye. Messrs. Allen and Hanbury (Plough-court, E.C.) also supply a novelty in the shape of ozonising tubes for administering ozonised air as inhalation, or for ozonising the air of rooms or hospital wards. The results of trials with cases of pulmonary tuberculosis and anæmia claim some attention. A remarkable increase in the percentage of the oxyhæmoglobin appears to result upon this treatment. It is impossible to enumerate the lengthy list of "recent additions" brought to the notice of the visitors by Messrs. Burroughs, Wellcome, and Co. (Snow-hill, E.C.) on their admirably designed exhibit. Suffice it to mention some which comparatively recently have found favour in the list of remedies now largely prescribed. Emol-Keleet, for example, an interesting preparation which we have already noticed, is a remarkably fine mineral powder containing a high proportion of steatite, and has been found of excellent service as a dusting powder for inflamed and weeping surfaces. It is also well adapted as a diluent for antiseptics and as a tooth powder. The useful styptic, hazeline, is prepared in the convenient forms of "cream," "snow," and suppository. Amongst synthetic remedies were agathin, an effective anti-neuralgic and anti-rheumatic; alumnol (naphthol-sulphonate of aluminium), a new antiseptic possessing the important characteristic of precipitating albumen and gelatine, which, however, are soluble in excess; diaphtherin (oxychinaseptol), whilst powerfully antiseptic, is without the caustic and corrosive action of phenol or the toxic properties of oxychinoline; dermatol, an excellent and odourless substitute for iodoform; uretin, another substitute for iodoform, which is said not to cause eczematous action; phenolsalyl, a powerful antiseptic mixture, composed of benzoic, salicylic, and carbolic acids; and, lastly, Knoll's diuretin, as its name implies, a diuretic consisting of a compound of sodium theo-bromine with sodium salicylate. An excellent solvent and vehicle for eucalyptus, pinol, menthol, camphor, thymol, and salol, amongst other interesting products of this firm, is paroleine, a colourless fluid and tasteless oil obtained by the careful fractional distillation of petroleum.

"Standardised preparations" constitute some of the features on the stall of Messrs. Southall Bros. and Barclay (Birmingham). Thus the belladonna preparations, containing definite proportions of alkaloids, represent an important development in pharmacy, while convenience and advantages secured by the employment of their concentrated tinctures, which can be diluted with the official menstruum with the greatest ease to the required strength, are patent. Amongst these tinctures are aconite, arnica, belladonna, conium, gelsemium, and orange. A useful collection of materia medica specimens, herbaria, &c., of service to medical teachers, students, and others, comprised not the least interesting section of this firm's exhibit, which also included in regard to new remedies granular effervescing preparations of lysidine and the same new uric acid solvent (described as a crystalline but very hygroscopic base obtained from ethylene-diamine) contained in aerated distilled water. "Ergole" is one of the new pharmaceutical achievements of Messrs. Oppenheimer (Worship-street, E.C.), which is described as containing all the principles of ergot. It is to be used subcutaneously or per os, and is claimed to be free from irritation or from any tendency to excite nausea or gastric irritation. In the same category may be included other standard concentrated liquors of this firm, which possess the advantages of being miscible with water, highly concentrated, and admitting readily of the low melting soft and supple constituent parts of pure dilution to any required strength. There should be mentioned also Messrs. Oppenheimer's malt preparations, which, by their palatability and general excellence, have taken high rank, to which they are entitled, amongst dietetic aids. Adeps lanæ was one of the most important of the preparations arranged by Messrs. Thos. Christy and Co. (Lime-street, E.C.). It is a pure wool-fat, containing largely wool-fat. It absorbs nearly 300 per cent. of water if desired, and being free from free fatty acids does not become rancid. The interesting derivative of quinoline known as analgen, and used largely now as an analgesic and anti-neuralgic, was also shown here, as was likewise that peculiar decomposition product, ortho-æthoxy-ana-amido-quinoline, which at times occurring in the urine gives it a bloody appearance. That the colour is due, however, to a quinoline derivative, and not to what appears at first sight as an alarming symptom, has been satisfactorily demonstrated. Various extracts, kola preparations, tinctures, and trochisci, and many of Stearn's novel preparations, including wine of cod-liver oil, hæmoferrum pilloids, for which Messrs. Christy and Co. are London agents, were also placed for inspection at this stall. The preparations containing pumiline—the essential oil distilled from the needles of the snow-grown pine of the Alps—which Messrs. Stern exhibit are of well-known value in throat and lung affections, while a liniment and ointment containing the same oil is claimed to be useful for the relief of muscular rheumatism or in the treatment of sprains &c. "Zalone lozenges" contain, in addition, a small amount of thymol. Liquor calcis iodinatæ is described by Messrs. Willows, Francis, and Butler (100, High Holborn) as a compound of lime and iodine which is preferable for use to the preparations containing free iodine where an irritant effect is to be avoided. It is much more satisfactory than tincture of iodine, it is stated, for injection into the enlarged thyroid gland in goitre and into strumous glands or joints, and serves favourably as an application to swollen glands or joints. Ferratin, described as the ferruginous element of blood and a chemical combination of iron and an albumen derivative identical with that found naturally in food; lactophenin, a new antipyretic-like phenacetin, but possessing the advantage of a pronounced sedative effect; and liquor sedans (hydrastis, viburnum, piscidia), which has been successfully used in hyperæmia of the female reproductive system, are amongst the recently acquired and important pharmaceutical and medicinal preparations of Messrs. Parke, Davis, and Co. (North Audley-street).

Specimens of ferratin were also to be found in the really elegant and imposing collection of Messrs. Ferris and Co. of Bristol, and with them several comparatively new and important remedies, such as acidum cetraricum, a bitter principle from liverwort, and suggested as a substitute for quinine; airol, a gallate of bismuth, with iodine also in its composition, useful, it is said, for burns and chronic ulcers; apocodeine, not an emetic as originally supposed, acting beneficially as an expectorant, especially for children, being besides a hypnotic, and producing sleep, it is stated, without the excitement of morphia; argentamine, an aqueous solution of phosphate of silver; and ethylene-diamine, a microbicide, which does not precipitate with albumen or chlorides and is useful in glandular abscesses and as an injection in gonorrhœa; auri et arsenici bromidum, prepared as a comparatively new therapeutic agent in the treatment of epilepsy, hysteria, Bright's disease, having also been employed in the treatment of sclerosis, tuberculosis, &c.; bromalin (bromethyl formine), containing 32 per cent. bromine), offered as a safe substitute for the inorganic bromides; carpaine, an alkaloid from carica papaya, the physiological action of which is similar to digitalis, but can be injected without producing, it is said, local irritation; hæmol and hæmogallol, prepared from blood, and used in anæmia and blood impoverishment; hæmol mercuro-iodate, described as a new remedy for syphilis, containing 12 per cent. of mercury and 20 per cent. of iodine, in combination with "hæmol"; biniodide of mercury solution, excellent in parasitic diseases; myrrholipe, an oleaginous solution of myrrh, which has been employed beneficially in laryngeal troubles of tuberculous origin;

Digitized by Google

naphtholate of sodium (microcidine), a compound of β-napthol and caustic soda, a powerful antiseptic, but feebly toxic; and, lastly, a petroleum emulsion of hypophosphites presenting many advantages. Subjects of our own analysis some time ago were the exhibits of Messrs. Salomon and Co. (Rainham, Essex)—viz., "purest chloroform" and "purest ether." We now learn that the purity of these products, as shown in our analyses, has since been confirmed by the excellent results of their employment in anæsthetic practice. In another place we have already pointed out the important and ingenious improvement which Messrs. Cooper and Co. (Gloucester-road, South Kensington) have effected in cachets; their sinapine tissue or mustard paper is an equally important advance. It is said not to blister the skin and is certainly clean and very neat, while its action is certain. The preparation known as liquor quininæ salicylatis of these pharmacists is also worthy of mention, since it is an elegant combination of quinine and salicylic acid, which has given excellent results in the treatment of chronic and atonic forms of gout and rheumatism. It has also been employed in migraine and trigeminal neuralgia, especially of dental origin, and as an antipyretic as well as tonic in influenza. A new use proposed for the tincture of adonis vernalis, prepared by Messrs. C. J. Hewlett and Son (Charlotte-street, E.C.), is to relieve obesity, while amongst new preparations made by this firm are alphol, which is decomposed by the pancreatic juice into salicylic acid and naphthol and gives relief in acute rheumatism, and cornutine, according to Kobert the active principle of ergot, which administered per os is said to be a safe method of exciting uterine contractions during parturition. In their list of improved pharmaceutical preparations this firm also include mist. hæmatoxyli co. conc. aromat, a successful combination, it is stated, for diarrhœa and dysentery.

Jeyes' Sanitary Compounds Co. (Cannon-street, E.C.) undertake the agency of some new remedies. Thus lysidine, the new solvent of uric acid, was discovered by the late Professor Hofmann in the products of distillation of ethylene-diamine. It possesses, it is said, five times the solvent power of piperazine and sixty times the solvent power of carbonate of lithium. Carnferine is described as an organic iron compound prepared from extract of meat, and contains 30 per cent. of iron. Three new iodine compounds—viz., nosophen, antinosine, and eudoxine—are said to be useful in certain diseases in effecting external and internal antisepsis. Migrainine (antipyrine, caffeine citrate) is considered to combine the physiological properties of both antipyrine and caffeine, and is accordingly employed with great benefit, it is stated, in migraine, headache, and kindred disorders. Lastly, symphorol is now comparatively well known as a diuretic producing increase of urinary secretion without secondary symptoms. Perhaps the most striking novelty of Messrs. Mackey, Mackey, and Co.'s (Grange-road, S.E.) exhibits were the "gelata," a name given to a series of elegant preparations having a clear and jelly-like consistence, intended for use as antiseptics and rubefacients in the treatment of skin diseases. The base is of a non-fatty character, is soluble in water, and easily absorbed and removed. The list includes boracic acid, carbolic acid, salicylic acid, camphor, chloroform, eucalyptus with or without carbolic acid, eucalyptus with coal tar or thymol, menthol, tar, and thymol. To this list we would suggest that biniodide of mercury dissolved in potassic iodide would be a useful addition, as a valuable application in certain diseases of the skin. The same firm's mistura bismuthi composita is well known as one of the best preparations of bismuth. The new preparations of cerium used as a specific for vomiting in pregnancy and other conditions, and as a nervine tonic, are also specially worthy of mention.

There were some excellent organic preparations on the stall of Messrs. Burgoyne, Burbidges, and Co. (Coleman-street, E.C.). Messrs. Arthur and Co. (Berners-street, W.) exhibited a good list of "new medicinal preparations made in accordance with suggestions and prescriptions of eminent members of the medical profession." Amongst these were a neutral, non-saccharine, non-astringent, and sterilised preparation of lime and iron, properties which indicate its value for children or patients with enfeebled digestive powers; a preparation of calcic chloride similarly devoid of objectionable properties; and the elegant gold compounds liq. auri brom. arsenatis, liq. auri brom. arsen. mercuratis, and liq. argenti arsenatis. The attractive exhibit of Mr. William Martindale, the excellence of whose pharmaceutical preparations are well known, bore striking evidence of the pace which the author of the "Extra-Pharmacopœia" might be expected to keep in accordance with modern developments. The gold preparations, a specially absorbent turf moss, the synthetic remedies, and nitroglycerine tablets, first introduced by this pharmacist in 1878, are worthy of mention. Improved Blaud's pills, called "iron jelloids," in which oxidation is prevented, were a noticeable feature of the exhibit of Messrs. Warwick Bros. (Old Swan-lane, S.E.), as was also "lactopeptine," a digestive powder containing lactic acid, hydrochloric acid, ptyalin, pepsin, and pancreatine, and prepared by Mr. J. M. Richards (Holborn-viaduct). Messrs. Read and Carnrick's new and interesting preparation, known as "peptenzyme," presenting, it is stated, in functional physiological activity all the digestive agents of the animal economy (stomach, pancreas, spleen, salivary and Brunner's glands, Lieberkuhn's follicles, and free nuclein), was exhibited amongst the products supplied by the Peptenzyme Company (Alfred-place-west, S.W.). The glands are extracted mechanically and without the use of acids and chemicals.

Besides the now well-known remedies exalgine (analgesic), diuretin-Knoll (diuretic), and papain (vegetable pepsin), Mr. Kühn (St. Mary-at-Hill, E.C.) showed tubes of ethyl chloride, now used largely to produce local anæsthesia and is also of value for the ready treatment of neuralgic pain. By simply unscrewing a cap a fine jet of the volatile liquid is expelled by the pressure of its own vapour within, and intense cold is produced by its evaporation upon the skin. For more extended operations a combination of ethyl and methyl chloride is very effective. Sublimated papers impregnated with definite quantities of mercuric chloride, since they are handy and useful for extemporising a powerful disinfectant fluid, should not be omitted from our notice. Messrs. Kuttnow and Co.'s (Holborn-viaduct) improved Carlsbad powder is now recognised as a valuable addition to natural aperient medicines, while the anti-asthmatic powder, made by the same firm, has since our last notice of it received abundant testimony of its effectiveness, as well as its harmlessness, in the treatment, as an inhalation, of asthma and bronchitis. It is a fragrant herb compound, but contains no lobelia or datura tatula, and may be smoked and the smoke conveniently inhaled in the form of cigarettes. In addition to the more or less new remedies—such, for example, as airol (iodoform substitute), gallobromol (a bromine preparation useful in blennorrhagia), thiol (a sulphuretted hydrocarbon oil suggested as a substitute for ichthyol), and thioform (another iodoform substitute), Messrs. Greeff & Co. (Eastcheap, E.C.) showed specimens of antivenomous serum taken from an ass or horse immunised against snake venom. Ten cubic centimetres for children and twenty cubic centimetres for adults are said to be sufficient as a prevention against the action of venom. It is supplied in phials, and its manufacture is supervised by Dr. Calmette, Directeur de l'Institut Pasteur de Lille (Nord). Mitchell's cold-drawn castor oil (the British Castor Oil Co., Victoria-street, S.W.) has already called forth our approbation, since it is as tasteless as castor oil can be, possessing a fine nutty flavour and increased therapeutic efficiency. Angiers petroleum emulsion with hypophosphites, again, has been critically examined in our laboratory, as the result of which we were able to report it as a specially refined oil of a purity consistent with its therapeutic requirements and containing the hypophosphites intact. Lastly, it is almost superfluous to add that the list of Messrs. Wyleys (Coventry) comprehended all the recent pharmacological advances, but amongst some of the several specialities shown we may mention the nasal bougies suggested by Dr. Richardson Rice for the treatment of hay fever, composed of cocaine, and those containing boracic acid or tannic acid for employment in ozæna and nasal polypi respectively; and the preparations of chekan used recently with good results in the treatment of phthisis. The pharmaceutical specialities, preparations, &c., and a series of medicaments were a feature of the exhibit of Messrs. Evans, Lescher, and Webb (Bartholomew-close, E.C.), while modern requisites were in evidence in the exhibit of Messrs. Francis Newbery and Sons (King Edward-street, E.C.). To these may be added the preparations of Messrs. Lorimer and Co. (Britannia-row, Islington, N.), comprising lacmagnesia, dermoplastin or eczema cream (boric acid, zinc, and bismuth), syr. hypophosph. co., ol. iodi, and ext. hamamelis dist.

(To be continued.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations, and having conformed to the by-laws and regulations, have been admitted Members of the College:—

Ashdowne, Wallace Charles George, L.R.C.P. Lond., St. Mary's Hospital.
Atkins, George Ernest, L.R.C.P. Lond., Firth College, Sheffield, and Queen's and General Hospitals, Birmingham.
Beadnell, Charles Marsh, L.R.C.P. Lond., Guy's Hospital.
Beddard, Arthur Philip, L.R.C.P. Lond., Cambridge University and Guy's Hospital.
Bekenn, George Henry Ernest, L.R.C.P. Lond., Mason College and Queen's and General Hospitals, Birmingham.
Belcher, James Arthur, L.R.C.P. Lond., University College Hospital.
Beven, Octavius, L.R.C.P. Lond., Durham University and Guy's Hospital.
Bill, John Francis, L.R.C.P. Lond., St. Bartholomew's Hospital.
Blachford, Jem, L.S.A. Lond., London Hospital.
Blake, Victor John, L.R.C.P. Lond., University College Hospital.
Breton, Moyle, L.R.C.P. Lond., St. George's Hospital.
Bridger, Sydney, L.R.C.P. Lond., University College Hospital.
Burnett, Leslie Burton, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Burns, William Thomas, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Byford, William Francis, L.R.C.P. Lond., Guy's Hospital.
Byrne, Peter Kevin, L.R.C.P. Lond., University College Hospital.
Caley, William Birch, L.S.A. Lond., University College and Royal Infirmary, Liverpool.
Carson, Herbert William, L.R.C.P. Lond., St. Bartholomew's Hospital.
Carter, Felix Bolton, L.R.C.P. Lond., University College, Hospital.
Cave, Francis William, L.R.C.P. Lond., University College and Royal Infirmary, Bristol.
Chapple, Robert Llewellyn, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds, and St. Mary's Hospital.
Chater, John Samuel, L.R.C.P. Lond., St. Bartholomew's Hospital.
Chilcott, Edward Smith, L.R.C.P. Lond., St. Mary's Hospital.
Coleman, Ernest, L.R.C.P. Lond., Guy's Hospital.
Coleman, James Jordan, L.R.C.P. Lond., Guy's Hospital.
Cook, John Howard, L.R.C.P. Lond., University College Hospital.
Cooper, Thomas George Duncan, L.R.C.P. Lond., Queen's College and South Infirmary, Cork.
Crace-Calvert, George Alfred, L.R.C.P. Lond., St. Bartholomew's Hospital.
Cran, Robert David, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Cribb, Harry Gifford, L.R.C.P. Lond., Middlesex Hospital.
Davies, John Edgar Philip, L.R.C.P. Lond., St. Mary's Hospital.
Daw, William Henry, L.R.C.P. Lond., London Hospital.
Dawes, John Alphonsus, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester, and Westminster Hospital.
Dawney, Archibald Hugh Payan, L.R.C.P. Lond., University College and St. Thomas's Hospital.
Deas, Frank, L.R.C.P. Lond., University College Hospital.
Denne, Francis Vincent, L.R.C.P. Lond., Westminster Hospital.
Dimsey, Alfred, L.R.C.P. Lond., University College Hospital.
Duffield, Ernest Alphonse, L.R.C.P. Lond., University College and Royal Infirmary, Bristol, and Guy's Hospital.
Eedle, Edward John, L.R.C.P. Lond., Charing-cross Hospital.
Ellis, Robert Mackay, L.R.C.P. Lond., St. George's Hospital.
Erhardt, Conrad Charles James, L.R.C.P. Lond., King's College Hospital.
Evans, Arthur Henry, L.R.C.P. Lond., Westminster Hospital.
Falkener, Lyon, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Fryer, Ernest Henry, L.R.C.P. Lond., St. Bartholomew's Hospital.
Gabell, Douglas Phillimore, L.R.C.P. Lond., Charing-cross Hospital.
Gale, Frederick William, L.R.C.P. Lond., St. Bartholomomew's Hospital.
Gerrish, Daniel Smith, L.R.C.P. Lond., University College and Royal Infirmary, Bristol.
Gill, Sutton Dudley, L.R.C.P. Lond., Mason College, Queen's, and General Hospitals, Birmingham.
Gillett, Henry Tregellis, L.R.C.P. Lond., Oxford University and St. Bartholomew's Hospital.
Grant-Wilson, Charles Westbrooke, L.R.C.P. Lond., St. Thomas's Hospital.
Griffiths, John Alban Kendall, L.R.C.P. Lond., University College, London.
Guest, Herbert Merrick, L.R.C.P. Lond., Cambridge University and Mason College, Queen's and General Hospitals, Birmingham.
Haines, Edward, L.R.C.P. Lond., St. Thomas's Hospital.
Hall, John Noakes, L.R.C.P. Lond., St. Mary's Hospital.
Hall, Joseph Percy, L.R.C.P. Lond., Owen's College and Royal Infirmary, Manchester.
Harman, Nathaniel Bishop, L.R.C.P. Lond., Cambridge University and Middlesex Hospital.
Harnett, Charles John, L.R.C.P. Lond., Guy's Hospital.
Hawthorn, Frank, L.R.C.P. Lond., Durham University, Newcastle-upon-Tyne.
Herbert, William, L.R.C.P. Lond., St. Thomas's Hospital.
Hope, John Lamplugh Allen, L.R.C.P. Lond., St. Bartholomew's Hospital.
Hounsfield, Sydney Coupland, L.R.C.P. Lond., St. Bartholomew's Hospital.
Hutchinson, Frederick Arundel Stewart, L.R.C.P. Lond., Cambridge University and London Hospital.
Irving, William, L.R.C.P. Lond., Cambridge University and Middlesex Hospital.
Johnson, John Robert, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool.
Johnson, Robert Macfie, L.R.C.P. Lond., University College Hospital.
Jones, Arthur Thomas, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool.
Jones, David Lewis, L.R.C.P. Lond., St. Bartholomew's Hospital.
Jones, Edward Thomas, L.R.C.P. Lond., University College Hospital.
Jones, George Kimball, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool, and London Hospital.
Jones, Murray Parry, L.R.C.P. Lond., Guy's Hospital.
Kenrick, William Hamilton, L.R.C.P. Lond., London Hospital.
Knocker, William Douglas, L.R.C.P. Lond., St. Thomas's Hospital.
Lamplough, Charles, L.R.C.P. Lond., Mason College, Queen's and General Hospitals, Birmingham, and St. Bartholomew's Hospital.
Lanphier, Charles William, L.R.C.P. Lond., Charing-cross Hospital.
Lansdown, Gilbert Harry, L.R.C.P. Lond., King's College Hospital.
Mann, Fairman Rackham, L.R.C.P. Lond., Middlesex Hospital.
Mann, Frederick William Slingsby, L.R.C.P. Lond., University of Durham and Mason College, Queen's, and General Hospitals, Birmingham.
Maxwell, Ernest James, L.R.C.P. Lond., Cambridge University and Guy's Hospital.
Moreton, Reginald, L.R.C.P. Lond., St. Thomas's Hospital.
Morley, Frank, L.R.C.P. Lond., St. George's Hospital.
Morris, Charles Edward, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool.
Mortimer, William Graddon, L.R.C.P. Lond., London Hospital.
Mulligan, Frederick William, L.R.C.P. Lond., Trinity College, Toronto, and University College Hospital.
Myler, John William, L.R.C.P. Lond., Middlesex Hospital.
Newbald, Clement Arthur, L.R.C.P. Lond., St. Bartholomew's Hospital.
Newton, Robert Earle, L.R.C.P. Lond., University of Glasgow.
Nicholson, John, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
O'Hea, James Patrick, L.R.C.P. Lond., St. George's and St. Bartholomew's Hospitals.
Pentreath, Leonard Norbourne, L.R.C.P. Lond., St. Thomas's Hospital.
Philipps, Arthur Edward, L.R.C.P. Lond., Guy's Hospital.
Phillips, Francis Addison, L.R.C.P. Lond., St. George's Hospital.
Phillips, Henry Arthur, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Power, John Hugh, L.R.C.P. Lond., London Hospital.
Reynalds, George Frederick, L.R.C.P. Lond., St. Bartholomew's Hospital.
Riley, Francis, L.R.C.P. Lond., Westminster Hospital.
Robinson, Edwin William, L.R.C.P. Lond., Westminster Hospital.
Rodocanachi, Ambrose John, L.R.C.P. Lond., University College Hospital.
Rowland, Walter John, L.R.C.P. Lond., Durham University and Guy's Hospital.
Ryan, William Bonner, L.R.C.P. Lond., Charing-cross Hospital.
Sanders, Alfred William, L.R.C.P. Lond., St. Mary's Hospital.
Sayers, Matthew James Hazlitt, L.R.C.P. Lond., St. Thomas's Hospital.
Scot-Skirving, Archibald Adam, L.R.C.P. Lond., University of Edinburgh.
Scott, Herbert Ainslie, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Shaw, Harold Batty, L.R.C.P. Lond., University College Hospital.
Shepherd, Ernest, L.R.C.P. Lond., St. Mary's Hospital.
Sheppard, Arthur Murray, L.R.C.P. Lond., Sydney University and St. Bartholomew's Hospital.
Shorland, Ernest Trevor, L.R.C.P. Lond., Guy's Hospital.
Smallwood, Robert Percy, L.R.C.P. Lond., Cambridge University and St. Mary's Hospital.
Smith, Albert John, L.R.C.P. Lond., Westminster Hospital.
Southey, Herbert Watson, L.R.C.P. Lond., St. Bartholomew's Hospital.
Spain, Charles Milner, L.R.C.P. Lond., University College Hospital.
Spillane, James Charles, L.R.C.P. Lond., London Hospital.
Squire, Maurice Frederick, L.R.C.P. Lond., St. Mary's Hospital.
Steward, Francis James, L.R.C.P. Lond., Guy's Hospital.
Stoner, Harold Boniface, L.R.C.P. Lond., Guy's Hospital.
Talbot, Alfred George, L.R.C.P. Lond., Edinburgh University and Middlesex Hospital.
Tench, Sidney Edward, L.R.C.P. Lond., Middlesex Hospital.
Thomas, Evan, L.R.C.P. Lond., University College Hospital.
Thomas, Nevill Everard, L.R.C.P. Lond., Middlesex Hospital.
Thornely, William, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
Tonks, Arthur Edwin, L.R.C.P. Lond., Mason College, Queen's and General Hospitals, Birmingham.
Towne, Hugh Rose Forster, L.R.C.P. Lond., Westminster Hospital.
Turner, Alan Charles, L.R.C.P. Lond., Middlesex Hospital.
Turner, Thomas William, L.R.C.P. Lond., London Hospital.
Wallis, Sidney Seymour, L.R.C.P. Lond., Guy's Hospital.
Wasson, Charles Robert, L.R.C.P. Lond., St. George's Hospital.
Wheatley, Rupert, L.R.C.P. Lond., Middlesex Hospital.
White, Sidney Hugh, L.R.C.P. Lond., University College Hospital.
Wilkinson, Arthur Norris, L.R.C.P. Lond., Westminster Hospital.
Williams, Charles Wellingham, L.R.C.P. Lond., St. Bartholomew's Hospital.
Wilson, Francis Kenneth, L.R.C.P. Lond., Westminster Hospital.
Wise, Harry Mortimer, L.R.C.P. Lond., Guy's Hospital.
Woolley, Fred Duke, L.R.C.P. Lond., Owen's College and General Infirmary, Manchester.
Woolley, Jasper Maxwell, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen having passed the necessary examinations, have been admitted by the two Colleges Diplomates in Public Health :—

Allen, Sydney Glenn (Surgeon-Captain, Army), M.R.C.S. Eng., L.R.C.P. Ed., St. Mary's Hospital.
Childs, Christopher, B.A., M.D. Oxon., L.R.C.P. Lond., M.R.C.S. Eng., St. George's Hospital, Oxford and Bonn Universities.
Chown, Francis, M.B. Lond., L.S.A. Lond., St. Mary's Hospital.
Fremlin, Heaver Stuart, L.R.C.P. Lond., M.R.C.S. Eng., Westminster Hospital.
Gepp, Maurice, L.R.C.P. & S. Edin., L.F.P. & S. Glasg., St. Bartholomew's Hospital.
Hopwood, Edgar Oswald, M.A. M.D. Oxon, University College, Owens College, and Royal Infirmary, Manchester.
Kerr, Daniel Oliver, M.B., C.M. Edin., Edinburgh University.
Larkam, Edward Thomas, L.R.C.P. Lond., M.R.C.S. Eng., Middlesex Hospital.
Lindow, Albert, M.R.C.S. Eng., L.S.A. Lond., King's College Hospital.
Norris, William Perrin, M.B. Melb., Melbourne University.

Von Wyss has been appointed Extraordinary Professor of Forensic Medicine and Toxicology.

SHEFFIELD ROYAL HOSPITAL.—The annual meeting of the Governors of the Sheffield Royal Hospital was held on the premises on July 31st, the Rev. H. H. Wright presiding. The secretary read the sixty-third annual report, which mentioned that the first portion of the new hospital had been opened, and that the financial position of the institution had greatly improved. The appeal sent out by the president (the Duke of Norfolk) since the last annual meeting had resulted in a sum of over £30,000 being either promised or received for the new building fund. Their Royal Highnesses the Duke and Duchess of York had graciously opened the new wing and laid the foundation-stone of future additions, and Her Majesty the Queen had been pleased to command that the institution should in future be known as the Sheffield Royal Hospital. During the year just ended there had been an increase of 333 in the patients, and an increase of £329 in the annual subscriptions, but the total income fell short of the expenditure by £395, and a large sum still had to be raised in order to cover the cost of building. The Duke of Norfolk was re-elected president, and Sir Frederick Mappin, M.P., and Sir Henry Stephenson vice-presidents.

THE POLICE SURGEONS' ASSOCIATION.—The annual meeting was held at King's College on July 30th, Mr. T. Bond being in the chair. A report from the council was read by Mr. Hopkins (hon. sec.), referring principally to the deputation to the Home Secretary in the early part of the year and its results. A vote of thanks to Mr. Asquith for his courtesy in receiving the deputation and for carrying out some of its recommendations before leaving the Home Office was unanimously adopted. The following officers and council were elected for the ensuing year :—President: Sir H. D. Littlejohn, M.D. Vice-Presidents: T. Holmes, F.R.C.S., and T. Bond, F.R.C.S. Treasurer: H. Nelson Hardy, F.R.C.S. Edin. Hon. Secs.: F. W. Lowndes, M.R.C.S. (Liverpool), and H. C. Hopkins, M.R.C.S. (Bath). Council: J. R. Baumgartner, M.R.C.S. (Newcastle), J. Paul Bush, M.R.C.S. (Bristol), G. Harrison, M.R.C.S. (Chester), W. O. Heslop, F.R.C.S. Edin. (Manchester), E. K. Houchin, L.R.C.P. (London), H. W. Roberts, M.R.C.S. (London), D. McDonnell, M.D. (Belfast), W. G. Lowe, M.D. (Burton-on-Trent), L. Maybury, M.D. (Southsea), W. M. Roocroft, L.R.C.P. (Wigan), C. Templeman, M.D. (Dundee), and S. Wolferstan, L.R.C.P. (Plymouth).

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

A NEW APPOINTMENT AT THE MIDDLESEX HOSPITAL.

WE notice in the columns of a lay contemporary an announcement of a new appointment at the Middlesex Hospital. Our contemporary then proceeds to give sundry personal details which, though highly creditable to the gentleman to whom they refer, should not, in our opinion, be inserted except in a professional journal. At the same time we feel certain that the paragraph in question was inserted without the knowledge or leave of the subject of it. Truly no profession suffers so much as ours from the mistaken kindness of would-be friends.

Anceps.—The condition being a *symptom*, there are numberless reliable works bearing upon it, for its history is the history of the parent disease. There is very little to be said about the condition on a separate entity, and most of the books treating of it in this manner are to be distinctly distrusted.

"THE FIRST NUMBER OF 'THE LANCET.'"

To the Editors of THE LANCET.

SIRS,—The letter of "Historical" in your issue of the 27th ult. raises a very interesting point, and one which I have taken not a little trouble to correctly ascertain for myself. I have not had the advantage of reading what Mr. Clarke, in his "Autobiographical Recollections," has to say on the subject; but doubtless his statement that the first number of THE LANCET was issued without a cover is entitled to be received with the greatest respect, looking to his lengthy official connexion with THE LANCET. I have a copy dated July 25th, 1829, which has a white cover, and I have been *told* (on what I consider good authority) that a cover was issued with the first number. Of course, it is a very difficult point to be settled at this distance of time; but if any of your readers could throw any light on the point it would be most interesting.

I might also add that very few copies of the original first number are now in existence. Even the British Museum is deficient in this respect. The original first number consisted of thirty-six pages. Pages 1 and 2 were occupied by the Preface; pages 3, 4, 5, 6, 7, 8, and 9 by Sir Astley Cooper's Surgical Lecture; pages 10, 11, 12, and 13 by articles on Politics, Enlightened Liverymen, Dr. Collyer, and the Drama; pages 14 to 28 by Medical and Surgical Intelligence; page 29 by Medical Extracts; pages 30 to 32 by Compositions of Quack Medicines and Table Talk; pages 33, 34, and 35, by an article on Southey the Laureate; and page 36 by Notices to Correspondents.

Many persons are under the impression that they possess complete copies of the original issues of THE LANCET; but my experience is that very few indeed have the originals of the first two volumes.

I am, Sirs, yours faithfully,

Aug. 6th, 1895. ANTIQUARY.

SMALL-POX IN THE STRAND.

THE following startling story appeared in an evening paper last week. "On Wednesday afternoon," writes a correspondent to the *Globe*, "I was walking along the Strand with a friend, who is a medical practitioner, when, seeing a man coming towards us, he remarked, 'That is a case of small-pox.' We stopped the man, who was rather shabbily dressed, and, after some conversation, ascertained that he had only been released from gaol that morning. The medical man examined him, and found that he was suffering from the disease, the case being a typical one. The man was shocked to learn this, and after some consideration it was decided that my friend should remain in charge of the patient while I went for a constable to see what could be done. On seeing an officer and relating the facts to him, he remarked, 'I cannot act, Sir, unless you are willing to give the man in charge.' The sufferer was quite agreeable, and although the doctor had an important engagement at the time he thought it better, in the interests of the public, not to fulfil it rather than to allow the man to remain in the streets. We, therefore, accompanied him to Bow-street. We told an inspector our business, but he refused to have anything to do with the case, saying, 'We do not want any small-pox here; you must take the man to Charing-cross Hospital.' I argued a little with him, but it was no use. The man was taken to the hospital by order of the inspector, but was not admitted. He was then sent to the Strand Union, where he was examined by a medical officer, who confirmed the view that he was suffering from small-pox. My friend received a police telegram the same night stating that the patient had been conveyed to an infirmary, and would be removed later to the small-pox hospital." It is, of course, well-known to all medical men in London that the Police do not know the working of the machinery which exists for dealing with such cases. The recommendation of the Bow-street inspector, unless it was founded upon disbelief of the diagnosis, reveals this patently.

Typhus.—British Medical Benevolent Fund (Mr. Edward East, Secretary, 16, Upper Berkeley-street, Portman-square); Royal Medical Benevolent College, Epsom (Mr. J. B. Lamb, Secretary, 37, Soho-square, W.); Society for the Relief of Widows and Orphans of Medical Men (Mr. J. B. Blackett, Secretary, 20, Hanover-square, W.); THE LANCET Relief Fund (Mr. E. Davies, Secretary, THE LANCET Office, 423, Strand, W.C.).

C. C. B. T.—Our correspondent has done all that lies in his power. The editor of the paper in question will probably make some explanation or correction where necessary.

A FUTURE COLLEAGUE!

To the Editors of THE LANCET.

SIRS,—May I ask your advice on the following case:—A. B. was some ten years ago convicted of forging the Matriculation certificate of a University, and was imprisoned for eight months. Since then he has kept a druggist's and chemist's shop, and has managed to pass all the examinations necessary for a medical diploma except the final. A petition has been sent to the local medical society signed by some registered medical men residing near A. B.'s shop, stating that he is about to undergo examination for the diploma of a certain licensing body; that he is not a fit person to become a member of an honourable profession; and that he has been carrying on an extensive unqualified practice for some time (of which no proof is offered except the fact that A. B. was censured severely by the coroner on one occasion for having attended a child which subsequently died without having been seen by a registered medical practitioner). The petitioners also pray the society to take steps to prevent A. B. getting his qualification. We are anxious to avoid making any false step that might lead the society into difficulties, and we would be greatly obliged if you will tell us what course could be safely taken, either by the society or by one or more of the petitioners.

I remain, Sirs, yours truly,

July 28th, 1895. HON. SECRETARY.

*** If the allegations against "A. B." can be proved to complete demonstration, it is clear that he is an undesirable person for an honourable profession; but the local medical society cannot prevent him from becoming qualified if he can pass the examinations. Nor can the General Medical Council do anything before he is a registered practitioner, as he is not within their jurisdiction. It would seem to us that at present nothing can be done. The facts might be laid by individuals to whom they are known, and certainly *not* by the society, before the body which is believed to be going to license "A. B.," and that body might consider him a wrongful person to admit to the examination; but that would be a very extreme step to take.—ED. L.

PRACTICE IN SOUTH AMERICA AND IN ALGERIA.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly tell me where I can find detailed information as to the conditions under which English medical men can practise in the Republics of South America and in the French colony of Algeria? I am, Sirs, faithfully yours,

Aug. 1st, 1895. S.

SERO-THERAPY IN DIPHTHERIA.

N. N.—For those who are in doubt as to the efficacy of this treatment Dr. Roux' *ipsissima verba* are these:—"Le sérum peut occasionner des éruptions passagères: il ne tue pas. Agissez même dans le doute. S'il s'agit d'un vrai cas d'angine diphthérique, le résultat sera presque toujours la guérison. S'il s'agit d'une angine simple, la santé n'en sera jamais compromise."

B.A., M.D.—We have recommended a form of long-term temporary assurance under which the premium would be considerably less than for a whole-term policy, but uniform while the policy continued in existence. More advantageous terms may be obtained when the premiums vary from year to year in accordance with the calculated risks, but, having in our mind more than one prospectus that has been brought to our knowledge, we can only impress on our correspondent the necessity of understanding the form clearly before assuring. In our issues of April 23rd, 1892, and Sept. 10th, 1892, we have published short notes upon the different companies, but for our correspondent's purpose any first-class company would surely serve.

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—It is highly amusing to one living across the sea to read the remarks in THE LANCET about titles. One would imagine some of these correspondents had very little practice—they spend so much time in discussing the title of "Dr." Your correspondent "Verax" has written a very personal letter, "Dubitator" evidently being a brother practitioner of whom he is jealous. He says: "As if anybody thought of comparing the M.D. of Aberdeen with that obtained at the University of London," &c. As an old Aberdeen man let me tell "Verax" that, so far as practical knowledge of the profession is concerned and ability to treat disease, the M.D. (Aberdeen) is quite as good as the M.D. (Lond.). The M.D. (Lond.) gets a more scientific education, but does not make a better practitioner. The late head of the profession in London, Sir Andrew Clark, the late Sir James Clark, and the late Sir John Forbes were graduates of the Northern University which "Verax" affects to despise. "Verax" displays great ignorance in saying that the M.D. could be got by "simply purchasing a return ticket, availing themselves of a northern train," and I refer him to the Students' Number of THE LANCET for the past twenty years, and I hope he will have sufficient manliness to acknowledge his errors and apologise. In my time Aberdeen possessed some surgeons of undoubted talent, Messrs Pirrie and Keith being the leaders. These two surgeons were very kind to students, often taking them to private operations. The first time I saw Dr. Pirrie "cut for stone" was in a house in Crown-street, Aberdeen, where an Australian student and myself assisted him. Knowing, therefore, a great deal about the Aberdeen school, I felt I could not allow an individual who evidently "did not know what he was talking about" to traduce my old *alma mater*. I have no idea of the identity of "Verax," but if a patient I should be sorry to place myself under the care of a medical man who would make such uncalled-for statements. Practising as I have been for many years in a Greater Britain, where all legally qualified men are styled "Doctors," and justly so, it seems to me childish to have such unseemly squabbles over a name. I have always believed that every man who has passed a satisfactory examination should be called "Doctor."

I am, Sirs, yours truly,

July 10th, 1895. M.D.

J. E. T.—There is only one institution where the sons of medical men receive educational advantages over and above other boys; but our correspondent's son is too old to make it worth while applying there. The curriculum of any good local grammar school should, with application on the student's part, make the passing of the examinations mentioned a certainty; and there are many schools in England where the tuition fees are very low—so many, in fact, that it is unnecessary to single out one or two by name. Other circumstances might be allowed to dictate choice of residence.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—During the absence of a neighbour I attended at the delivery (only) of one of his patients. The lady now calls upon me requesting my attendance at her second confinement. After explaining that I cannot because I attended for her regular medical man, she tells me she will not have him again, and presses me to undertake the case. What should one do under such circumstances?

I am, Sirs, yours truly,

Aug. 8th, 1895. ETHICS.

*** These questions cannot be decided quite offhand, and often there are circumstances which prevent any direct answer being possible. If "Ethics" is clear that he has in no way unfairly supplanted his neighbour, there can be no reason why he should not take the case. We mean that there would be nothing dishonourable in doing so, though we can quite understand that it would be highly repugnant to him, as it would be, we are glad to believe, to most of the profession. Would it not be possible for him to see his neighbour and talk the matter over amicably? For sensible men the attitude of the patient would be seen to mean nothing offensive.—ED. L.

THE PROBLEMS OF CHILD-SAVING IN NEW YORK CITY.

THE Secretary of the Children's Aid Society in New York reports that the Society has twenty-one day schools and twelve night schools, with a daily average attendance of 6200 children. These schools are given by private munificence, and are supported partly from the public funds and the balance by donations from charitable people, and cost the Society 130,000 dollars during the year to maintain. The children are taught such manual work as they are fitted for—such as cooking, household work, sewing, paper folding, drawing, modelling, and wood working. Only those children are allowed to attend who are so poor, ragged, and neglected that they cannot go to the public schools, or where there is no room for them in the public schools. This work has been in operation for forty years. More than 100,000 children have been started aright in life from the schools of the Society. The "placing out" system, with its corps of trained, experienced and careful agents, finds good homes in the country for these homeless ones. Forty thousand young and middle-aged men and women are now living honest, prosperous lives in Western and Southern States, who would otherwise have remained to drift about New York.

Mr. H. Cuthbert.—The donation to the Townshend Fund has been received and forwarded.

"SANITAS" IN EMPYEMA.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if any of your readers can give me some information with regard to the use of "Sanitas" for washing out old empyema cavities. I am, Sirs, yours faithfully,

Newcastle-upon-Tyne, Aug. 4th, 1895. HENRY S. BAUMGARTNER.

ALFRED CARTER, Limd., 47, HOLBORN VIADUCT, E.C.

INVALIDS' FURNITURE, BATH CHAIRS, & PERAMBULATORS.

Patronised by Her Majesty's Government in India, Malta, Australia, China, the Cape, and throughout the world. Adopted by the Hospitals Association, London, for the Street Accident Service of London. Adopted by the Bournemouth Ambulance Corps for use in the Town.

This Ambulance was first exhibited in the year 1889 at the competition held in the Great Hall of St. Bartholomew's Hospital, when it was unanimously admitted to be in every respect the most suitable carriage for the conveyance of injured persons. After being in actual use for three months the police submitted their report, which was unanimously and unexceptionally in favour of Alfred Carter's Viaduct Ambulance Litter.

GREAT IMPROVEMENTS IN

SOUTHALLS' SANITARY TOWELS

FOR LADIES,

Which supersede all others for ECONOMY, EFFICIENCY and COMFORT.

THE LANCET of June 15th, 1895, says:—

"In their Improved Towel the tendency in the flow of the discharge to contract its area is counterbalanced, and the inconvenience of imperfect absorption—dammed-up discharge, with consequent roughened edges of the pad, and perhaps overflow soiling of the clothes—is remedied."

THE BRITISH MEDICAL JOURNAL of June 8th, 1895, says:—

"It possesses three distinct advantages: it is more absorbent, more comfortable in wear, and from its shape is more cleanly in use."

THE MEDICAL PRESS AND CIRCULAR of June 29th, 1895, says:—

"From the point of view of comfort and cleanliness, the improved article appears to be as superior to the original pad, as the latter was to the old-fashioned napkin."

The Retail Prices of SOUTHALLS' IMPROVED "SANITARY TOWELS" are the same as the old make, viz:—

Size 1	1/- per packet of One Dozen.	Sizes 3 and 4	2/- per packet of One Dozen.
,, 2	1/6 ,, ,,	,, X	2/9 ,, ,,

SPECIAL PRICE TO THE PROFESSION.

Southalls' Sanitary Wool Accouchement Sheets, at 1s. and 2s. each. Southalls' Accouchement Sets, at 10s. 6d. and £1 1s. each.

Wholesale from—**S. MAW, SON & THOMPSON, Aldersgate Street, London.**

And all Wholesale Druggists and Druggists' Sundriesmen, and from the Manufacturers and Patentees—

SOUTHALL BROS. & BARCLAY, BIRMINGHAM.

ABSTRACT OF

An Address

TO

GRADUATES IN MEDICINE IN THE UNIVERSITY OF EDINBURGH.

Delivered on August 1st, 1895,

BY W. S. GREENFIELD, M.D. LOND., F.R.C.P LOND. AND EDIN.,

PROFESSOR OF PATHOLOGY AND CLINICAL MEDICINE IN THE UNIVERSITY.

GENTLEMEN,—It is my pleasant duty and privilege to convey to you the congratulations of my colleagues and of the University on the attainment of your degrees and upon the varied honours and distinctions bestowed to-day. To those of you who have attained the degree of M.D. we offer our sincere congratulations, not only in that you have elected to reach the fullest medical standard of our University, but that so many of you have contributed Theses of high value to medical science. It is no small thing to be graduates of this University, to share the inheritance of so many noble traditions, and to belong to the school of so many eminent men of the past and present. You are no mere licentiates of a medical corporation, but members of a University which in the past has been, as we trust it will continue to be in the future, distinguished in all branches of learning. During long years the combined influence and mutual interaction of the various Faculties have moulded and elevated the teaching of the whole. Many of you have directly profited by the teaching of professors in other Faculties than that of medicine, but even those who have not done so must have felt their influence. Remarkable as is this University in the long combination of distinction in medicine with that in divinity, law, philosophy, and science, it is hardly less unique in its relations to the citizens of this noble and beautiful city. For long years, in place of antagonism between town and gown, the University has been amongst the chief glories and most dearly cherished objects of solicitude of the inhabitants. The fathers of the city, its eminent citizens, its wealthy men, have vied with one another to foster and develop it. Apart from higher interests, the results of their munificence and care are seen to-day in the noble buildings, both of the University and the Royal Infirmary, in which you have received your training. You owe, then, a debt to this city as well as to the University, which should be an incentive to each one of you to see to it that by your life and influence you do nothing to tarnish the fair fame of either. Nay, I would go further, and say that by all means in your power you should aim to promote the renown and success of the University, and to increase its material prosperity.

You have chosen a profession higher, perhaps, than any other, hardly excepting Divinity. It is full of noble traditions and memories, of possibilities of good to your fellow men, and of self-culture in all the highest qualities of man. You are rightly proud of your choice, and you will do well to retain your high ideal of your position and duty. All the more will you find this essential, since you will meet with many temptations to a lower standard in your own life. Still more will you find that your view is not shared by the majority of those around you. If you imagine that the public entertain a like view of the position and objects of your profession, you will soon be undeceived. In theory they may, and here and there some noble souls may recognise it, but for the most part your views and aims will be misunderstood. If, for example, you try to introduce sanitary improvements, you will probably be charged with a desire for notoriety, with ignorance of the common facts of life, and, above all, with a desire to raise the rates. Obloquy and suspicion will often be your meed, instead of gratitude and regard. Your monetary compensation, if any, will be grudged, and possibly be cut down below that of a common scavenger. The picture in Charles Kingsley's "Two Years Ago" is true to the life to this day. I speak from intimate knowledge in many instances. "A meddlesome conceited fellow," they will say, "fresh from college, full of new-fangled ideas." "As if we did not know what water we should drink, what air we should breathe; what we should do with our sewage, how we should feed and clothe our children," and so on. "Our fathers lived to a good old age without any of your new notions. What did for them will do for us." In such matters and a multitude of others you will find that the public, in spite of modern education and enlightenment, will oppose or thwart you. Even the diffusion of knowledge, the abundance of popular medical literature (so called), the ready access to medical works, due partly to their wide advertisement, will often act prejudicially to your treatment of patients, especially amongst the better educated classes. Indeed, it is often with them that the dangerous "little knowledge" is a serious barrier to successful treatment. To face such difficulties will often tax all your endurance and courage. Only by patience, tact, and forbearance can you succeed, whether in dealing with individual cases or with matters of wider interest. But, beyond this, there is one prevalent opinion which will come in to mar your influence. Money is, for the vast number of men, the first object in life; this, and not character or ability, is the standard of success. Do not be surprised if you are believed to have this as your first object. If it is really so I pity you. Not only may you fail utterly in your object, but you will be led into ways which must bring you loss of character. I mean real, not reputed character, and which may mar your success in the alleviation and cure of disease. It will lead to much bitterness and sorrow, to misunderstandings and quarrels with your medical brethren, to a lowering of the dignity of your profession.

[Professor Greenfield here emphatically cautioned his audience against making pecuniary success their main object in life. He urged on them the advantages of literary culture, and continued:]

In the practice of your profession you will necessarily be exposed to many temptations and meet with many difficulties. Time forbids any full reference to these, but there are one or two on which I would, before we part, say a few words of counsel. Every medical man is in a relation of peculiar confidence to his patients and their friends. There are some facts which he must know, both as to patient and family, which are sacred confidences. There are others with regard to which he must exercise a wise reticence, even to the patient himself or to his nearest friends. And no task is more difficult sometimes than to know when to speak and when to be silent. But beyond this there is one rule, too often forgotten, that a practitioner should never talk about his patients or their diseases to others. There are some obvious exceptions—where you may silence false rumours, for instance. But, as a rule, it is only at the request, or with the sanction, of the patient or his friends that you should speak at all. I cannot too strongly urge you to cultivate this rule of silence. Once break through it and you will find it hard to stop, but let it be known that it is your rule, and you will retain the confidence of your patients and the credit of your profession. You will often be tempted to speak so long as morbid curiosity and gossip, those two most inherent and devilish of common vices, exist; the guise of sympathy, the bad example of some prominent men, the prying eyes of the world, to whom no details of inner life are sacred nowadays, will tempt you; and you will be blamed if you will not divulge in private life what all the world considers itself entitled to know about public men. If you knew what one could tell of the mischief wrought by gossip, and especially by gossip founded on the sayings of men who should know the facts, you would shrink from all possible chance of doing such harm. Let your sense of honour guard your lips, and even keep the doors of thy mouth from the wife of thy bosom. When pressed for information it is a good rule to say, "It might do no harm for you to be told, but I am the last person to give you any information." I will not insult you by supposing that you will talk about your patients, with the idea that it will benefit your practice, by saying, for instance, that Lord So and So is under your care. It is not my business to teach you the arts of quackery. There are plenty of teachers. Not less difficult is it to know how to convey truth to your patients and their friends. Medical men are often blamed for concealing the truth from patients, even when asked directly. Much of this popular error arises from the fact that the presentation of truth is amongst the most difficult of acquirements.

The most perfect portrait is not that which presents every detail so that it can be studied with a microscope, but that which conveys the living likeness to the casual beholder. How few artists, how few writers, can succeed in this. It is no sophistry, but practical truth, that you must endeavour to convey the right impression as seen from the standpoint of your hearer. And in doing so you must keep in view the practical object for which you are consulted. To tell a man that he has heart disease may torture him with fears of sudden death, may lead him to give up his work and to live a life of misery and apprehension, when you know that he may live a long life and do active work, if due precautions are taken. It is your duty, and must be your anxious study, so to convey the truth that it may enter his mind in a way which shall give him hope and courage, and lead him to take such precautions and live such a life as will conduce to both health and happiness; otherwise, as one has often seen, he may, after long years of misery, discover that you in your eager desire to be truthful, and, perhaps, from over-confidence in your diagnostic powers, have done him more injury than his disease. How many cases of this kind one could relate did time permit. But I pass on to mention another closely related point. Bear always in mind that not only cannot the subjective and objective coincide, but that, from many points of view, a patient must always be regarded as aberrant. His mental condition cannot be yours. You see matters in that dry light of truth which Aristotle commends. The patient's fears, anxieties, wrong ideas, and speculations cannot be yours. He watches your every phase of expression; a puzzled or anxious look on your face may convey to him a sentence of death. Medical men, when ill, are the worst patients in this respect. One look may efface all that you can say. Hence no endowment is better in a doctor than a calm, cheerful, sympathetic manner, especially if combined with clearness, decision, and thoroughness in directions and candour in speech. "A merry heart doeth good like medicine," and is often a better sedative than all your drugs. Be anxious if you must, but let it be as a stimulus to more careful investigation, more watchful care in yourself. Beyond this, remember that sickness makes a man not himself. The higher his intelligence, the greater his activity, the wider his responsibilities, the more intolerable is sickness. It is not the physical but the mental pain which is hardest to bear, the risks of suffering to others, the apprehension of imagined or real woes. More than this, the mental and moral condition, like the pathological processes of disease, often revert to the type of early life. A child's ailments are often revealed by peevishness, a baby cries from hunger or pain oftener than from innate depravity. And a good, wise, and high-souled man, or a loving, patient, considerate woman may suffer tortures from the most trivial causes in sickness—e.g., a picture hung askew, or a spot on the wall. "We, then, that are strong ought to bear the infirmities of the weak." A medical man must exercise the fullest patience, consideration, sympathy, and control of temper. I have known instances where, forgetting this, perhaps himself wearied and overwrought in mind and body, a medical man has spoken harshly, or even has left a patient in advanced stages of disease, because of some imaginary slight. If you would avoid life-long remorse, apart from the discredit of such things to yourself and your profession, I beseech you to remember that "Better is he that ruleth his spirit than he that taketh a city," or distinguishes himself in diagnosis. In your relations to your medical brethren you may also meet with difficulties. One should perhaps pass these in silence, or speak with bated breath, in the presence of the public. But the fact that there are sometimes dissensions amongst medical men is but too well known, and the public judgment is warped by knowledge of the exceptions, and ignorance of the rule of brotherly feeling and action. That we are not only no better, but rather worse, than other men in this respect is a common belief. It is no answer to say that amongst those whose profession is higher, and whose creed is one of universal charity, the *odium theologicum* is a common and flagrant fact. Whatever may be our theory, however stringent our codes of medical ethics, it is unquestionable that ill-feelings and misunderstandings do too often mar our charactor, and will, I suppose, so long as we are human. Amongst the most frequent causes are those which relate to the distribution of patients, or rather clients. Medical practitioners, especially early in life, are charged with seeking to get the patients of others. The general idea that people are divided into the clients of Dr. A. and Dr. B.: that if Dr. A. is asked to see, and does see, anyone in a family which Dr. B. usually attends, he is a supplanter, to be scorned and avoided by Dr. B., and that Dr. B. may justly refuse to see anyone in that family again, even in an emergency, are rules sometimes supposed to govern practice. I do not say whether this is right or no, I record the fact. And there are too many thorny questions, too many intricate problems, which arise in connexion with such matters for me to attempt to deal with them. But this I will say, that I know of no rule of law, common or statutory, which empowers a medical man to claim an exclusive right to attend any man or his family, and that the public in general does not understand the high ground of privilege which is sometimes claimed. Believe me, gentlemen, the only real, sure, and lasting bond of union between medical man and patient is that of mutual confidence and respect. The exhibition of jealousy and distrust of the character and motives of one's fellow-practitioner is more likely to lead to loss of confidence than to its increase. Readiness to consult with others when desired is not likely to lose a patient. A man will not readily part with the services of one who has been in his confidence and has helped him or his family in times of trouble. Exclusiveness, suspicion, jealousy, evil report of one's neighbours, will only destroy confidence where it might otherwise be retained, and a patient may long to be released from a bondage which he did not seek. In such cases some people will go long distances to consult others, concealing or denying the fact that they have been under treatment, and often they do this to their own detriment, as well as to that of their medical man. I have often been astonished that patients have not enjoyed the advantage of consultation with medical men in their own neighbourhood, who could far better advise with their own medical attendant, and have found the explanation in the fact of mutual distrust and the idea that such a step would be resented. I have dwelt upon this point because I judge it to be one of the most urgent practical importance. But pray do not misunderstand me. It is one of the most stringent and primary rules that no medical man should under any guise, directly or indirectly, interfere with the conduct of a case which is under the care of another, unless consulted by him. Moreover, you will remember that I say this to guide your own conduct, not to influence your opinion of the conduct of others. There are salutary rules, established by long experience and concurred in by the wisest and best of our profession, which should regulate your conduct to your fellows, even if you cannot as yet see their justice or wisdom. Need I add that to comment upon the treatment or diagnosis of others, a habit we are all prone to, is not only a crime but a blunder. No man can judge of a case which he has not seen, and reports or rumours should never be trusted or be the ground of comment. Leave such criticisms to those who cannot know how deep is the anxiety, how great the difficulty, of the actual diagnosis and treatment of disease. You may think that in what I have said I have given a counsel of perfection unattainable by mortal man. But if you do not aim high now, you probably never will. And finally, gentlemen, let me commend to you the quality of *thoroughness*. Far more mistakes are made in diagnosis, and consequently in treatment, by want of thoroughness, than from ignorance. It has been our effort to ensure that as you have received a complete scientific training, so you should be thorough and methodical in all your clinical work. You cannot be too rigorous with yourselves in this. Cultivate the habit of thorough investigation in your earlier years, and you will gain a power of perception which will stay with you in the busier years of practice. There is genius in medicine as in other spheres, but the highest genius is in the power of careful and thorough attention. It is thus that the great men in all science have gained their renown. Every patient is a new and complex problem—not a mere "case"—with his own heritage of tendencies, his own habits, his temperament, his past life. Study all these with care, and you will develop powers which will make your success as medical men. It is not always the brilliant students who become successful and distinguished, but those who with good ability, assiduous care, and perseverance train what powers they have. Let those who have been depressed and daunted by their failures at examinations remember that the race is not always to the swift or the battle to the strong. Their difficulty in grasping facts or unravelling problems may have been due only to slow development, and they may discover new powers and attain high qualities by steady and persevering work.

ON THE RECOGNITION OF PERIPHERAL NEURITIS AND SOME POINTS IN ITS TREATMENT.[1]

BY JAMES CAGNEY, M.A., M.D. IREL., M.R.C.P.,
IN CHARGE OF ELECTRO-THERAPEUTICS, ST. MARY'S HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS; ASSISTANT PHYSICIAN, NORTH-WEST LONDON HOSPITAL.

THIS paper does not pretend in any way to be a systematic treatise on the disease to which it refers. The subject has been dealt with so ably in many text-books and monographs that ample instruction upon all points awaits the investigation of the curious, and is doubtless already in the possession of my hearers. None the less I would urge that to every man who with certain opportunities thinks and works at one subject over a length of time there are likely to come ideas, not necessarily new or different from those of others who have laboured in the same field, but ideas at least with an emphasis originating in his mind and determined by his experience; and such ideas, when they possess him strongly, it is often useful to impart. Now, if it were granted—and I fear the admission is hardly justified—that most medical men were as well able to distinguish with certainty the presence and the extent of a peripheral nervous lesion as they are, say, to recognise a typical case of nephritis, it might still be said with truth that, whereas everyone has his mind open and directed to the possible presence of the latter in any given case, but little thought or apprehension is usually devoted to the former. Comparing the two conditions, it will certainly be conceded that there prevails a want of familiarity with the nervous disease. It is one of the ideas which experience has emphasised for me that a recognisable lesion of peripheral nerves is a very common thing—far more common than is often believed. It crops up everywhere, sometimes overlaid and hidden in a mass of more obtrusive symptoms; sometimes—as after typhoid fever, acute rheumatism, or influenza—the remnant of a disease more directly threatening life; sometimes a tedious complication to a surgical injury, often existing alone as a formidable and eventually fatal disorder. In all of these circumstances it may be, and often is, overlooked from a want of familiarity with the conception of it. It is with a sense of this fact that I have chosen to treat of the recognition rather than of the diagnosis of peripheral neuritis. I shall have to refer to the question of diagnosis as I proceed; but my purpose chiefly is to enjoin a vigilance, a preparedness of mind, by which the condition may be sought in all likely circumstances; to indicate some of these circumstances as experience has impressed them upon me; and finally, to make some remarks bearing upon treatment generally and in particular cases.

One of the commonest and most looked-for of the causes of neuritis is alcoholic excess. Yet in this the condition may be overlooked among the many disorders which, springing from the same source, are often present with it.

CASE 1.—I was asked to see a female patient reported to be in a state of coma and in danger of immediate death. There was a history of intemperance, but the patient had been for months an invalid and under supervision. Consequently alcoholic poisoning was not suspected. The liver was cirrhotic, and there were ascites, diarrhœa, and enormous hæmorrhoids. She was insensible when I saw her, but the lightest touch on the inflamed hæmorrhoids elicited an expression of pain. The breathing and the heart's action were good, and the imminence of death was not apparent to me. The comatose state, maintained during the day, gave place at night to periods of violent delirium, and both mental states were of a character which suggested alcoholism. I observed, also, that there was complete foot-drop, the knee-jerks were absent, and pressure upon the extensor surface of the forearm occasioned the expression of pain. The patient was receiving a few ounces of brandy to maintain her strength; I advised the withholding of alcohol entirely, and she made a partial recovery, but died a week later from pneumonia. An experience of this kind teaches one the necessity in such a case of looking closely at each of the symptoms, even when they are grouped together in a seemingly obvious and familiar whole. The possible bearing upon treatment of the inference then drawn needs little comment, especially when, as here, the administration of alcohol may be a large part of that treatment. Akin to this subject is one point upon which I am tempted to dwell. Outside and beyond the fact that patients are not always candid, and are accustomed diligently to conceal their moral infirmities from the physician whose help they have sought, there is a further difficulty of judgment based upon our own conception of what may suffice to produce a toxic state. It is true that in my own experience, where I have thought that I have eventually learned all the facts, it has generally appeared in cases of alcoholic neuritis that the imbibition of quantities of alcohol sufficient to satisfy the most exacting inquirer has been an antecedent. Nevertheless, I have my mind open to the belief that in certain persons a relatively small quantity will produce nerve symptoms which an inveterate dram-drinker will fail to develop.

CASE 2.—A young man aged twenty-two was brought to me by a colleague on account of a weak heart and a sluggish liver, which he was reputed to have. The liver was enlarged a finger's-breadth downwards, and the abdominal wall in this part was tender. The patient was flabby and anæmic, with a lack-lustre eye, and slow in his movements. He was the subject of habitual constipation. Physical examination of the heart revealed only a hæmic murmur. I had satisfied myself on these points when the patient observed incidentally that he had for some days been troubled with muscular rheumatism and with tingling and numbness in the extremities. There was tenderness of the muscles in the arm and leg and a degree of anæsthesia in the hands and feet. The knee-jerks were present. Notwithstanding this fact, and that the patient denied alcoholic excess, I gave the opinion that he was in an early stage of neuritis. He admitted a moderate indulgence in sherry between meals, and I further made allowance for a probable suppression or attenuation of the truth, but thought it likely that with a portal system blocked, a feeble circulation, a weak glandular organisation and defect of the emunctories, even moderate indulgence might have produced a toxic state. Within a week I was called to this patient. He was then unable to leave his bed; the knee-jerks were absent, to return slowly after four months, and in the meantime he passed through an extremely severe attack of alcoholic pseudo-tabes. I am greatly indebted to the good fortune which enabled me to observe this case from its earliest beginning. It is probably a unique experience. The ultimate result of my inquiries showed that in this case there was no need to assume a special susceptibility, and it may have been so with the female who was the subject of the first case cited here. I think not, however. I attribute great efficacy to what I may call the summation of causes in the production of toxic neuritis. This summation may be the summation of a single cause from a defective elimination of the poison, such as one may assume to exist where the hepatic function is impaired by an impediment to the circulation or by disease of any sort. Indeed, the usual association of liver trouble with habitual drinking itself suggests this, and the same association might seem to imply that there was generally at work the double factor of susceptibility to nerve poisoning, and of accumulated poison from defect of elimination. Amongst men, however, it is by no means those whose livers bear the heaviest traces of drinking who are most apt to succumb to neuritis, and in women, who are the commonest sufferers, neuritis usually precedes gross changes in the liver. Among women it is perhaps the anæmic and ill-nourished who offer the least resistance, and amongst men it is decidedly those of feeble circulation and what is often described as an inherited liver. I believe that in some of these even small habits of tippling may be thoroughly effective. It is difficult to apportion the factors in causation, but we are all led by our own views in judging a cause, and may sometimes question the effect without due regard to other evidence. According to present knowledge the most important element is always, of course, individual susceptibility, and occasionally a light may be thrown upon this indirectly. There is what is called a family of neuroses, and there is a class of allied states which seem to entail a special proneness to defect of nervous vitality. I can recall a remarkable instance in which the

[1] A paper read before the West London Medico-Chirurgical Society on May 3rd.

Digitized by Google

allied neuroses had committed a terrible onslaught on a single family.

CASE 3.—On March 4th, 1891, a young man aged twenty-four came to me at the Hospital for Epilepsy and Paralysis. He was obviously in great extremities of poverty. He had still about him an air of gentility and a kind of refinement, which in another class we sometimes ascribe to good breeding. There was some uncertainty, too, about his name. When young he had been in hospital for vertigo and again for something the matter with his eyes. For the latter he had been given cod-liver oil and quinine. His complaint when I saw him was wasting, weakness and painful cramps, occasional giddiness, but in particular a remarkable hyperidrosis, which rendered him unfit to follow his occupation. A few questions made it plain that the family history was full of neurotic incident, and the young man's father sent me in writing the following remarkable statement. One grandfather died from apoplexy; one grandmother from asthma, the other grandmother from phthisis; the father himself had spinal paralysis; the mother was then an inmate of a woman's hospital, and had been subject to hysteria major; one brother had hip disease, and another lupus; one sister was phthisical; one brother died from fits; a sister died from phthisis; a young brother was delicate; one sister was hysterical; and, lastly, one brother was reputed to be healthy. This brother I had a curiosity to see, and at my request he attended. I was little surprised to find that he inherited his full share of affliction. He exhibited exophthalmic goître in a pronounced degree and subsequently came under my care. One of a family such as this is readily the subject of any form of nervous collapse. I could cite from my notes many instances of such summation of susceptibility. I choose one in which for epilepsy and paralysis the evidence, though weighty, is more scattered.

CASE 4. A man aged forty-two attended at the Hospital for Epilepsy and Paralysis in October, 1894. He had imbibed great quantities of spirits as was, he said, the custom in his trade. He had never had syphilis. He had been ill off and on for four years, and this he attributed to influenza. His actual condition dated back six or seven weeks, consisting in weakness and wasting of the legs, cramp in the calves, foot drop, and absence of knee-jerks. I believed it to be a case of alcoholic paralysis. The patient had had writer's cramp for twelve years. The dynamometer registered 50 with the right hand and 70 with the left. He had had four children, who died at from two to four years of age two from phthisis, one from diphtheria, the cause of death of the fourth not being known. The writer's cramp, the early deaths from phthisis and diphtheria probably neuritis indicate a soil in which the seed of destruction would quickly grow. More interesting, perhaps, as a variety of summation of cause are the instances in which two or more toxic agents are known to co-operate. The influenza poison and gout are both well-known toxic agents.

CASE 5. A man aged forty-eight lately consulted me. He had never had gout, but on both sides his family abounded in the diathesis. His father and mother had fallen victims to it. Two years previously he had had an attack of influenza, and when sufficiently recovered to get up he staggered in walking. There were now exaggerated knee-jerks and ankle-clonus, and it was probable that this was the remnant of a myelitis. There had been foot-drop on one side, atrophy, and tenderness, and there was still a slight degree of reaction of degeneration to attest a peripheral lesion. The coexistence of lead poisoning with gout is too common to need notice. Indeed, I think that the gouty toxine can be found to be active alone or with other agents in a great number of cases of neuritis amongst men. Its efficacy by itself is beyond dispute, though very often overlooked.

CASE 6.—A man aged fifty-four was seen by me in August, 1887. He had formerly been subject to acute attacks of gout. For some years he had escaped these, in consequence, as he believed, of taking an Italian nostrum in the shape of pilules, which are well known to be therapeutically inert. He was an obstinate man, and it is a question whether his immunity was a result of suggestion. When I saw him his arteries showed extremely high tension, the optic discs were anæmic, and he was in a state little short of melancholia. The left foot dropped; the electrical reactions showed degeneration in the peroneal nerve, and the knee-jerk on that side was absent. This lasted for a considerable time; delusional insanity developed, and recovery ensued after the lapse of two years. There may be noticed here a fact well worthy of attention—the concurrent affection in a characteristic manner of the central and peripheral nerve elements. We are too prone to parcel out our conceptions of disease and to pigeon-hole them each in its small compartment. Nature works otherwise, and if we would study her processes we must follow her methods in this. The physiologists, in a commendable appreciation of mathematical forms, used to speak of the nerve cell as the "neurological unit." There is a tendency nowadays to larger views; and the so-called unit is the neuron. This is a nerve cell with all its processes—the aborescent processes as well as the nerve fibre all the parts which together with the cell are mutually interdependent. The extension of terms is decidedly a step in the right direction; but, after all, the neuron is but an anatomical unit. In pathology it is unsafe and inexpedient to confine one's attention within even this limit, for we cannot know the extent of functional interdependence. It is probable that a collapsing nervous system yields at points along its whole length. It may be too much to say that every poison which causes peripheral degeneration produces also a characteristic effect upon the higher levels of the nervous system, but an association of this kind is common and is well worthy of close study. The psychical type will often throw a useful light upon a case of peripheral paralysis. It will sometimes afford the key to difficult diagnosis, and suggest a line of treatment. The troubled sleep and stupor alternating with a timid, yet violent delirium which bespeaks alcohol may under some circumstances be misinterpreted. If, however, as it often happens, this is accompanied by peripheral paralysis, the nature of the poison is clearly evident. The first case quoted here is an instance in point. So with case 6, only that the series of events was more complicated. The vascular changes from retention of uric acid might be deemed sufficient to produce the symptoms by anæmia, but so limited a paralysis is not known to occur from anæmia. Again, the pallor and attenuated arteries of the ocular fundus, bespeaking malnutrition of the brain, might well bring about psychical disturbance; but such disturbance in anæmia is apt to be placid, to decline into torpor. There was here what may more justly be regarded as an exaggeration of the irritability and discontent of the gouty paroxysm. I am led by these remarks to refer to the question of hysteria complicating organic nervous lesions. The coincidence should always be looked for, and in some cases may be said to be almost inevitable. Such cases are principally those in which a strong neurotic propensity is known to exist.

CASE 7. I was asked to see a woman in good circumstances and of a markedly neurotic family, who for some months had been bedridden with paralysis and exaggerated tremors of the lower limbs. The disease had been taken to be disseminated sclerosis. The arrangement of zones, and patches of anæsthesia and hyperalgesia, led me to believe that the paralysis was what is called "functional." There was, however, a contracted pupil and wasting of the thenar muscles on one side, and these gave a reaction of degeneration. The distribution of pain also on that side of the trunk suggested a local irritation; and a careful examination showed mobility and displacement of the first dorsal vertebra—a condition very competent to cause these symptoms. To my mind it became at once probable that the more equivocal symptoms—paraplegia, tremors, &c.—were functional rather than due to a separate systemic lesion of the spinal cord. The subjects of lead poisoning are peculiarly apt to be also hysterical, and it is most necessary to distinguish between the organic and the functional in such paralysis as may be present.

CASE 8.—A lad aged seventeen was lately under my treatment at St. Mary's Hospital. He was unable to walk from paresis of the legs had incomplete wrist-drop—a paralysis of the whole of one upper extremity and of the muscles of the chest-wall on that side. He was much emaciated. Errors of sensation were in the direction of hyperæsthesia. The patient was very emotional. There was also marked buccal anæsthesia and clavus. The use of electrical tests showed that a small part of the extensors of the forearm was alone directly implicated. The lad had been exposed to poisoning by lead, and to this the organic paralysis of the extensors was attributed; the rest was put down to hysteria. He became too ill to attend, and some time later I encountered his body by chance on the post-mortem room table. He had died from tuberculous disease of the intestines.

In this connexion—the association of functional with organic nervous disease—one is reminded more forcibly than at other times that the term "functional" is only provisional, and that the condition which we call "functional" must properly be regarded as one in which an organic change, lesion or defect, though certainly present, escapes our present means of investigation. We cannot imagine disease without a definite material cause. Now, if this be so, organic disease itself must differ in respect to the evidence upon which its character is supposed to be based—must differ in respect to the certainty with which we know that two different instances have the same causation and are one and the same thing. Now of all diseases of the nervous system the degeneration of the peripheral nerves, which we call "peripheral neuritis," is the most definite, certain, and recognisable entity. Take, for instance, a cerebral tumour or a patch of sclerosis in the spinal cord. Such a thing is known partly as an induction from certain physiological facts, partly because certain symptoms have been found in a number of instances to have been present during life where these conditions were found post mortem, and the certainty that they will be again found in a given instance depends upon the precision of the symptoms. Take another instance of another class—Bright's disease. The vascular and retinal changes, the dropsy and malnutrition so constantly present, are very distinctive. But how greatly the certainty of a diagnosis is increased by the discovery of albumen in the urine! And it is a notable thing that, whereas we can refer the other symptoms with sufficient plausibility to the changes defined in every case where a necropsy is made, we have not even a respectable theory, though we have many speculations on the subject of albuminuria. The cause of the second sound of the heart is a matter of dispute, yet its modifications afford the surest evidence and measure of disease, and we call them "physical signs." Albuminuria, too, may be called a physical sign, and its value as evidence depends upon the constancy with which it occurs in nephritis. Reverting to organic nervous disease we have symptoms or reputed symptoms in all; in peripheral neuritis alone we have a physical sign of absolute and unerring accuracy, a sign obtainable at will, which bespeaks degenerative changes in the nerve fibre as plainly as if the fibre had been stained and mounted and submitted to examination under the microscope. Hence, if I am right in my contention that the disease is common, formidable, and infinitely more amenable to treatment than is Bright's disease, it is surely incumbent upon medical men to be provided with the means of a certain diagnosis. It would be a matter of shame—thanks to examining boards, an impossibility—for any practitioner to be ignorant of the ordinary tests for albumin; how many are there who are versed in the electrical tests for degenerating nerve and muscle? I am not going to speak of the symptoms of peripheral neuritis—many and unequivocal as they are—but a word upon its physical sign, the reaction of degeneration, cannot be avoided.

The "reaction of degeneration" is the term used to describe the behaviour under electrical stimulation of a muscle or considerable group of muscle fibres when the motor nerve of the latter is undergoing destruction or repair. Under such circumstances this reaction is never wanting. Moreover, the pathological character of the condition to which it testifies is always essentially the same, and admits of no kind of ambiguity. The condition may originate at the central cell or at the terminal organ, or it may constitute a lesion in the course of the nerve fibre; but wherever it begins there will be from that point downwards a definite morbid change in the neuro-muscular elements, a change which has been exhaustively studied and which is very well understood. To be able to recognise this change at any moment during life is clearly a matter of great importance, and this can be done by the intelligent use of an electrical current. There are many kinds of current, and there are differences in the physiological effects of each. We are concerned here with two only—the two which are of most general use in medicine. These are the constant or galvanic and the induced or faradaic current. The physiological effects of these two currents differ remarkably. It may be said that they have only one such effect in common—namely, that stimulation of a healthy nerve or muscle by either will cause a contraction in the muscle, and since this effect is produced only in health it is, from a practical point of view, of secondary importance. When used as a test to ascertain the condition of the nerve by watching the effect of the current upon the muscle, these two forms of electricity must be carefully distinguished, must be thought of as two different things. This will appear presently. Now as to the manner in which a current can be made to stimulate a nerve. It is impossible in the living body to imitate the physiological method of stimulating the excised muscle-nerve preparations upon which the facts of electrotonus have been worked out. The depth of the nerve beneath the skin, the diffusion of the current, the uncertainty of its path amongst the tissues, prevent the application of a current having a known direction in the nerve. Nor is this needed. What is imperatively required is that we shall be able to bring the nerve or muscle being examined under the influence of the current, and that in the case of the constant current we shall be quite certain of submitting the nerve to the separate action of the positive or the negative pole as we wish it. This is necessary because the effects to be observed are polar effects and differ characteristically with the pole used. It is always requisite that both poles be attached to the body, so as to bring the latter within the circuit. To give precision to the pole used locally this is carried by a small electrode, while the other, the indifferent electrode, is a very large one and is placed at a point anatomically as far as possible from the part under investigation. In most cases the indifferent electrode is placed on the episternal or epigastric region. When this is done the path of the current may be represented by a cone, and in proportion to the length and sectional area at the base of this cone—in proportion also to its nearness to the apex—will be the certainty that the nerve or muscle is submitted to the unmixed influence of the pole used locally, of the electrode which represents the apex of the cone. So much it is necessary to say for the sake of clearness, and, it being premised that we can apply a faradaic or a constant current and obtain the effect of either pole at will, the rest may be stated shortly. I will add that the question of polarity does not arise in the case of a faradaic current, for the poles are not distinguishable. I will take this current first and dispose of it. In health, if a faradaic current be applied to any part of a motor nerve or muscle, a tetanic contraction results. In disease, degeneration—and the so-called "inflammation of nerves" is merely a degeneration—a faradaic current wherever applied will fail to give a contraction. Thus the entire absence of faradaic contraction in a muscle is a certain sign that there is a lesion somewhere in the neuro-muscular tract—that is, somewhere not higher than the group of cells in the anterior columns of the spinal cord. Let it be noted well, however, that the presence even of a powerful contraction under faradaism does not exclude such a lesion. In many cases, and in peripheral neuritis especially, there may be, side by side and intimately mingled in the same muscle, healthy fibres with others undergoing change; the contraction of the first will then mask the inactivity of the latter, and in such a case a negative test can prove nothing. Again, the absence of a faradaic contraction may mean, besides degeneration, the entire destruction and absence of nerve or muscle substance, and for this reason, also, it is indispensable to have a test which will distinguish the two conditions. The test which would best meet these ambiguities would be one in which there would be no contraction only when the nerve or muscles were destroyed, while the contraction in health and in degeneration would offer a recognisable specific difference. Such a test is afforded by the constant current. Given a healthy nerve and muscle, the stimulation of either with either pole of the current causes a quick, lightning-like contraction whenever the current is made or broken, and this contraction occurs with a weaker current when the negative pole is used than when the positive is used. Let it be noted now what happens if the nerve or muscle has been injured and is undergoing degeneration or repair. In the first place, one cannot stimulate the nerve at all. Its faculty for transmitting the stimulus is gone. To obtain any result the electrode must be placed directly over the muscle. When this is done and the current made, the positive, not the negative, pole is found to be the more efficient stimulus. Further—and this is by far the most significant difference—the contraction is no longer quick and lightning-like, but, slow, long-drawn, and exhibiting a remarkable vermicular progress. If in a muscle there are both healthy and impaired fibres, the difference between the two contractions is invariably evident to the practised eye, and the presence of the slow vermicular movement, even in a few fibres, is absolutely diagnostic.

From these remarks it is clear that to predicate a reaction

Digitized by Google

of degeneration from the behaviour of a muscle to the faradaic current alone is a delusion and a fallacy; yet I have repeatedly seen the inference drawn by accomplished and skilful physicians. The fact must justify so long an exposition of what should be a familiar topic. Obviously all this applies only to motor nerves, and, equally obviously, sensory nerves are liable to the morbid change under consideration. I have elsewhere urged that a great number of cases of sensory neuritis are undoubtedly treated and spoken of as "neuralgia," and I have insisted upon the expediency of making a clear distinction between the two. Since, however, most peripheral nerves, if not entirely motor, are mixed nerves, and since the most limited display of the reaction of degeneration is conclusive, the test is almost invariably applicable.

CASE 9.—I was asked to see a young woman who more than a year previously had had influenza, and since then had suffered severe pain in one shoulder. She had been given a host of the usual remedies for neuralgia without effect, and the constant pain had been telling severely upon her general health. Examination revealed tenderness radiating backwards and forwards from the point of emergence of the sensory branches of the circumflex nerve upon the surface of the deltoid, and scattered fibres of that muscle were found to exhibit the reaction of degeneration. A neuritis of the circumflex was thus made evident, and local treatment, including the application of the positive pole of a constant current, effected a cure in a few weeks. A case of this kind, in which the nutrition of a large and superficial muscle is implicated, is one in which, with the proper means, an error of diagnosis is impossible. Without such means—that is, without the careful application of electrical tests—I think that anything like a certain and positive conclusion is unobtainable. In the case of the deltoid particularly, and of any muscle so situated in regard to a large joint, the presence of paralysis, atrophy, and muscular tenderness would not decide the matter, for these conditions are found constantly attending even slight lesions of the joint. The case seems to illustrate very well the importance of what I have called the "physical sign." It suggests, however, another reflection. I think it is a matter of the gravest doubt whether neuralgia—that is, a central affection declaring itself by local pain—can ever be restricted to the distribution of a single nerve. The trigeminal nerve may be an exception, and so posssibly are other cranial nerves whose ganglionic origin is distinct; but I would hesitate to speak of a circumflex neuralgia. The predominance of pain in the area of sensory nerves, while there is no obvious improvement of motor function, should not be construed as neuralgia but a diligent search should be made with electrical tests in the region of motor nerves derived from the mixed trunk. There are conditions in which neuritis of sensory nerves greatly prevails over that of motor nerves, and in which pain is more prominent than anæsthesia. Syphilis seems to be one of these, and it is this fact, probably combined with neglect or inefficiency in the use of the constant current as an aid to diagnosis, which has led some to doubt whether a syphilitic neuritis exists.

CASE 10.—A married woman nearly forty years of age was sent to me for treatment. There was a history of typhoid fever and of malarial fever, but no questions were asked on the subject of syphilis. The present illness dated from a time about four years previously, when for twelve months or so the patient used to vomit immediately on taking food, but had no nausea. About this time there was a sore within the mouth, afterwards extending to the outside of the lower lip and leaving scars. From the description of this sore and the appearance of the scars it seems to have resembled herpes. The sore was seen by several very eminent authorities, and I gathered that the idea of syphilis was not entertained. There was no syphilitic skin lesion when I first saw the patient. The remaining facts I transcribe from my notes.—Nov. 14th. Present condition: Severe headache constantly, with pain on pressure over place of emergence of supra-orbital nerve on both sides. Pain over deltoid and on pressure over trunk of circumflex nerve; pain on pressure in two spots over the dorsal spines; pain down the triceps, over the external condyle, and on pressing the radial nerve against the radius there is pain in the distribution of the nerve. All this is symmetrical, but of much greater degree on the left than on the right side. The pain is greatly intensified periodically at night, between one and two o'clock. The spleen is enlarged and tender. Electrical examination shows faradaic excitability, normal everywhere, but preponderance of the positive stimulus in the extensors in the left forearm, and a somewhat sluggish contraction there (slight R.D.). The patient has lately had cramps in the left thigh. Nov. 21st: The patient has attended daily except yesterday. The treatment has been the prolonged application of the anode over the tender points. On the first occasion the points over the circumflex nerve were alone omitted, and it was only in that part that pain continued. Headache, which had never failed for six months, completely disappeared. The first night the patient woke at the usual time—about 2 A.M.—but had no pain. This exemption continues. When a current of 10 to 15 milliampères is passed with the anode over the tender points of the supra-orbital nerves the sensation is described as pleasant and soothing. On one occasion the deltoid was rubbed vigorously in addition to electrification. That night there was severe pain in the region of the circumflex nerve, and this was afterwards gradually subdued by the anode. Ichthyol ointment is also rubbed in.—Nov. 22nd: Pain in the deltoid has ceased and given place to stiffness. Investigation of right arm shows tender points in (1) the lower part of anterior triangle of neck, (2) over emergence of circumflex in the quadrilateral space, (3) over insertion of deltoid, (4) in triceps posteriorly over the musculo-spiral groove, (5) over external condyle, (6) at the interval between the internal condyle and olecranon, and (7) beneath the belly of the supinator longus. There is intense pain on pressing the radial nerve between the tendon of the supinator longus and the bone. This pain radiates down the back of the wrist and hand. The radial nerve can readily be felt and is probably enlarged. There is severe paroxysmal pain in the left side of the thorax corresponding to three intercostal spaces. Treatment continued. Dec. 2nd: Two days ago all pain in the limbs had ceased, and there remained only occasional pain and tenderness on right side of forehead. One day's treatment was then omitted. For the first twenty-four hours there was no pain. In the next, pain recurred but its periodicity was changed; it occurred in the evening. There was pain in the left shoulder at bedtime, but a good night's rest. Patient has also been taking quinine and arsenic for some days. Dec. 12th: No treatment for four days. Patient had a chill two days after her last visit, and the same night had intolerable pain in right arm and head—less in left arm. Pain in head was relieved by camomile fomentation. Those pains better, but still persist. There is great pain on pressure over the head of the radius in front, also over a point about the middle of the posterior edge of the deltoid, over the acromion and over the olecranon. Tender points in scalp as before. All these points and the arm generally treated with anode. Dec. 13th: Pain relieved absolutely till bedtime, when there was some uneasiness in the arm, but a good night followed. In the morning some headache, more diffused, and tenderness had shifted down so as to underlie the eyebrow. The electrical reactions were taken very carefully. There is in both arms, especially the right, a marked preponderance of A.C.C., but the contractions were not obviously sluggish. Stimulation of the radial nerve with anode in any part of its course where superficial caused a tingling sensation all through its distribution, and a vigorous contraction in the extensor carpi radialis and in the forearm extensors. Treatment of painful points with anode as on yesterday and previous days. Dec. 14th: R.D. in extensors still more marked. The motor point of the extensor carpi radialis, observed yesterday, appears to be in one point in the course of the radial. This point is on the radial side posteriorly and about three inches above the styloid process of the radius. Treatment as before. Dec. 15th: Last night before bedtime excruciating pain in right arm, localised chiefly in extensors in forearm and at a point on the posterior edge of the acromion. Patient, according to advice, took seven grains of quinine in phosphoric acid. Pain was greatly relieved almost directly, but lasted some hours though much diminished. Little pain this morning. No headache last night. To-day there is a red papular rash in irregular patches, like those of herpes on the point and upper aspect of the shoulder. Colchicin and lithium bromide are now taken regularly and the limbs are kept warmly wrapped. Dec. 20th: On 16th severe attack of diarrhœa and nausea, for which no cause assigned, lasting three days. Given chlorodyne, sulphuric acid, and quinine. No pains. Dec. 21st: Much pain in right arm last night. March 2nd: Patient has been away. Pains in right arm as before. Left free from pain. Has now a sore fissuring the angle of

Digitized by Google

the mouth on the right side and extending outwards on the inner side of the cheek. This is decidedly specific. Patient says that she considers this to be the same condition that she had before coming under my notice." All other treatment was suspended, large doses of biniodide of mercury were given, and a cure shortly took place.

I have related this case at great length for various reasons. In the first place, it sets out a great part of the local treatment which I find useful in neuritis, and I shall conveniently refer to it when dealing with treatment. Then it is shown by the final event—a specific sore—and the cure obtained by the use of biniodide of mercury to have been, at least, in part, a syphilitic condition. If the history of malaria, the periodicity of the pains, and the efficacy of quinine introduce an element of uncertainty, the instance is *pro tanto* a good one of the summation of cause of which I have spoken above. That the condition was a neuritis, not a neuralgia—as it had been, and generally would be, termed—is plain from the morbid reaction in the forearm extensors; and the comparatively inconspicuous share of motor implication bears directly upon the question as to whether syphilis does cause peripheral neuritis or not. I think the answer should be that it does very commonly, but that it tells most often and most obviously upon the sensory nerves—just as the trophic lesions of syphilis so often involve the skin alone. It would be safe I believe, in all cases to treat similar pains in a syphilitic subject as peripheral, but if certainty of diagnosis is wanted it can be had only by a very careful investigation of the muscular state of the patient. The examination may have to be repeated often and often, or the morbid change, from being so slight, will escape detection. In this case every drug that is supposed to relieve pain had been tried ineffectually; two only gave any relief—namely, quinine in large doses and mercury. The latter cured the disease when its nature was made known; the former relieved paroxysms without curing the disease. It is therefore that I suggest an added cause of the neuritis in malaria which the patient had had years before, but which had not since troubled her; that, however, the condition was essentially syphilitic I doubt not at all. The paroxysmal thoracic pain mentioned under Nov. 22nd is remarkable. I have met with it elsewhere. I quote from another case, that of a man who admitted syphilis and who infected his wife and children. Severe "pains were in the right arm and forearm, in the back below and beneath the left scapula and extending forward to the sternum in the situation of the seventh, eighth, and ninth ribs. In the latter place the pain came on in spasms of great severity, and could be induced at any time by standing up." A hyperæsthetic zone having a similar distribution occurs sometimes in hysteria, and there the condition was called "pleuralgia" by Briquet. The difficulty of determining the peripheral character of the lesion is not confined to those cases in which it affects the sensory nerves of the skin and other superficial parts almost exclusively. One meets with cases of severe muscular pain in which the cause appears to be of the same nature without anything comparable to the same wide-spread degeneration that an equal degree of pain would almost certainly imply in, say, alcoholic neuritis. Such cases are sometimes mistaken for functional cramp. The importance of recognising their true character depends upon the fact that they are infinitely more tractable than functional cramp and more dependent on treatment. They occur chiefly in girls of a nervous organisation. I have two under my care at present. In neither is there any cutaneous pain or anæsthesia. One was attributed to the exercise of polishing work.

CASE 11.—The other is the case of a young woman aged twenty, who plays the violin, and she referred her pain to this. She has suffered for four years. The pain is of a dull, aching character, situated in the muscles on the extensor surface of the right forearm and radiating to the back of the second and sometimes of the first finger. It occurs spontaneously, but follows almost any movement, and in particular that of the bow in playing. At first the movements of supination and pronation were directly painful, and at that time there could be felt in the situation of the orbicular ligament an elastic swelling and crepitus. I inferred that there was inflammation about the ligament and was not surprised to find that the sufferer had been a too enthusiastic player of the game of lawn-tennis. I could at first find no undoubted evidence of muscular degeneration. The treatment I adopted was to rub in to the forearm vigorously a preparation of iodide of sodium with soap liniment over the site of a patch previously vesicated; then to apply the positive pole in this part to promote absorption of the drug by cataphoresis, and at the same time to allay pain. The limb was then swathed in pine-wood wool, bandaged, and carried in a sling. This treatment answered well. When the pain disappeared it became necessary to counteract a slight degree of flexor contracture by more energetic galvanism and faradaisation. In rubbing the extensors firmly I noticed that when pressure was made on a certain point a short, sharp contraction affecting only the second extensor tendon took place. This directed me to a closer inspection of that part of the extensor communis, and I found that there was a galvanic, as there was a mechanical, over-excitability, and all the evidence of a degenerative reaction in that limited part of the muscle. Why pain was referred from the corresponding part of the muscle to the finger itself I am unable to explain, but medicine is full of such mysteries, and the best profit is gained in observing the facts.

I have dwelt too long upon points which, however interesting, may seem to have but little practical import. It has been my object, however, to try to direct attention to the everyday and commonplace character of an affection which is much mixed up with the incidents that are encountered in practice, and I have endeavoured to point it out by an association with other circumstances which constantly engage attention. I have omitted discussion of the symptoms which are more apparent and more familiar, and I have confined myself to that which is most decisive but least generally available for want of knowledge. It seems to me deplorable that there should be a class of specialists devoted to electro-therapeutics. It is not so in other countries, and the example of such men as the Remaks, Eulenburg, Erb, Charcot, and a great number more, who have held a knowledge of the physiologically established principles of medical electricity to be but a small part of the equipment of an educated physician, may well be followed amongst us. In time it certainly will. For the present I would urge that diseases of the peripheral nervous system, but little complicated, growing every day in importance, and constituting, as they do, or should do, a large part of the responsibility of the practitioner,—I would urge that these, at least, should be taken from the domain of any specialist whatever. If it is clear that the means of recognising them is within everyone's reach, it is no less true that they are of all diseases the most manageable and the most amenable to treatment. Still, just as it is but seldom possible to form a true estimate of their nature and extent without the use of electrical tests, so it is always impossible to treat them adequately without employing electrical methods. These are not the conditions which lend themselves to the manipulations of the charlatan, and in which the *vis medicatrix naturæ* throws its cloak over the blunders of the incompetent. Nor is there anything empirical—otherwise then all medical knowledge is empirical—in the procedure best adapted to their cure. This procedure is based upon the accepted conclusions of the most eminent physiologists; it partakes of the strength of Pflüger's laws—it must be modified by circumstances within the observation of the physician, and if he will take the trouble to inform himself concerning the agent he has to use he will be repaid by an ever-varying and absorbing interest in the problems to which he has at least a serviceable clue. In speaking of the treatment of peripheral neuritis I would desire it to be understood that there is no specific. Nothing must be neglected. The primary underlying cause will be met by any of a host of remedies, therapeutical or hygienic; diet, abstinence, the application of a suitable temperature, change of climate, of occupation, and other circumstances in the environment,—all or any of these may have to be enjoined; and if I pass them over it is only for want of time and because they are already sufficiently appreciated.

I come to speak of one remedy which bears in a manner more direct than any other upon any disease whatever upon the state of degeneration in the peripheral nerves—I mean the use of electricity. And as in dealing with electrical tests I had to point out that there was the broadest distinction between one current and another, so here it must be enforced that there is even greater difference in their application therapeutically. It is a common notion that electricity medically considered is an agent to make the muscles jump. I have already said that this, the most obvious, is the least valuable effect of the current, and that the current which produces it most forcibly—the current which tetanises, the

Digitized by Google

interrupted current is of least account in medicine. Nevertheless, it is the best known and the most used by the haphazard practitioner who buys his instrument and obtains instruction in its use from the maker. The product "electricity," thus loosely thought of, is most often derived from the crude source of an induction apparatus. It is perhaps because a coil makes a noise when it is working and relieves the operator of the necessity of being able to check its work by its physiological effects, also because by its noise and pain and tumultuous contractions which it causes it satisfies both the operator and the subject that something is being done. It is chiefly, no doubt, because its use requires no knowledge, while that of the constant current demands a little. Whatever the reason, this confusion of ideas on the subject of electricity is as unfortunate as it is discreditable at the end of the nineteenth century. I can recall an instance of a poor woman suffering from convulsive tic who was daily subjected to the torture of a strong interrupted current, and this over a period of six months. The pain might have been—and in other hands afterwards was—allayed by the judicious application of the positive pole of a constant current, but the other applied to the periphery of sensory nerves is initially a source of pain, and in painful states an intolerable aggravation. From the point of view of treatment, as of diagnosis, the constant current is very much the more important, and this invaluable property of soothing pain is intimately concerned in the production of its beneficial effects. A good instance of its power in this way may be seen in the notes of Case 10, which I have purposely transcribed at considerable length. I am not disposed to enter into a discussion of the manner in which the positive pole of a constant current controls pain. It is sufficiently well understood, and is a deduction from the principles of electrotonus. I will content myself with quoting from Dr. Michael Foster's "Text-book of Physiology": "Besides their theoretical importance the phenomena of electrotonus have also a practical interest. ..... If the current be of adequate strength the irritability may be so much lessened that nervous impulses cannot be generated in that part of the nerve, or cannot pass along it. Hence by this means the irregular contractions of muscles known as 'cramp' may be abolished. Similarly, by bringing into a condition of an electrotonus a portion of a sensory nerve in which violent impulses are being generated, giving rise in the central nervous system to sensations of pain, the impulses are toned down or wholly abolished and the pain ceases. So, on the other hand, we may at pleasure heighten the irritability of a part by throwing it into katelectrotonus. In this way, properly applied, the constant current becomes a powerful remedial means." This statement is amply borne out by clinical experience. There are eminent authorities who discountenance the use of electric currents in what are reputed to be inflammatory conditions of the nervous system. The current, according to them, is an irritant of the inflamed nerves. Now, applying this dogma to any particular case, there are two assumptions which need to be made good. Let that particular case be peripheral neuritis. Is it an inflammatory state? It is necessary to recall the very recent date of our acquaintance with this condition and to allow for preconceived ideas derived from an unproved analogy with inflammatory states of the spinal cord. When Charcot taught that the lesion in anterior poliomyelitis was primarily one of the motor ganglion cells it seemed natural that changes quite similar in the axis cylinder process should be called inflammatory also; but Roger, Damaschino, Roth, and others have assailed Charcot's position with success, and it is now practically abandoned. The more recent works of pathologists upon peripheral neuritis make in a similar direction, and it is probable that where inflammation is a factor it is inflammation of interstitial and vascular structures, not an inflammation of the nerve substance itself. It is safer to regard the affection of the latter as a degeneration, attended with a loss or perversion of function. And, again, is there any proof that an electric current can under these or other circumstances be a nerve irritant? Absolutely none. Possibly the phenomenon of tetanic contraction under the influence of an interrupted current has led to the ill-considered supposition that a disturbance takes place in the nerve comparable to that in the muscle. Such a supposition is far from justified. The most careful experiments have failed to show that any heat is generated in a nerve when even a very strong current is carried through it, and the structure of the nerve as we know it is such as to preclude the idea of considerable molecular changes during the time it is exercising its function. In all this the nerve and the muscle present the broadest possible contrast. The contraction is a muscular, not a nerve, phenomenon. It takes place not in virtue of nerve energy, but in virtue of its transformation into muscular energy, not in the nerve, but in the muscle. Finally, in states of degeneration an interrupted current is altogether inert at the periphery—sufficient proof, surely, that it at least is not irritant. In such states it is the constant current only which has any effect. It is true that a contraction can be caused by its use in a particular way, but also a very strong current can be applied to a motor nerve, either in health or disease, without causing a contraction. The statement, as quoted above, of an eminent physiologist will serve to indicate broadly the ways in which it may be made serviceable. Its special application to clinical purposes is necessarily the subject of an elaborate technique of which the fundamental principles are the excitant action of the negative and the sedative action of the positive pole. I can testify to the efficacy of electrotherapeutics applied by this light to the treatment of neuritis, and I cannot urge too strongly my conviction that the time to resort to electrical treatment is the earliest and most acute stage of the disorder. I know that I am at variance with all but a very few upon this point; but if others will abandon the attitude of timidity and inaction for one of intelligent interference they will certainly obtain convincing results.

I have said more than once that in the disease under consideration the interrupted current has no effect on the periphery, and I have tried to make it clear that I mean no muscular effect. I believe it is quite otherwise in regard to the nerve. This current is there also without effect in the sense of any kind of reaction at the periphery, but that its effect upon nutrition at the centre is very considerable there is ample evidence. In the acutely painful condition called "sciatica" the strongest induced currents are borne without inconvenience. So in the remarkable state known as "anæsthesia dolorosa" the current so painful in health is usually tolerated freely; and in both it does good. In a sciatica which has been allowed to become chronic strong faradaisation should be the routine treatment. While upon this subject I will call to mind that a characteristic of peripheral neuritis is generally a limitation of the structural changes to the extreme ends of the nerves. I have tried to show that the morbid terminations can be influenced in almost any way by the appropriate use of galvanism, and I repeat that the comparatively healthy central parts are still subject to stimulation by either current. This fact should serve as an important guide in practice.

I will conclude these remarks by disclaiming the pretension that any one set of measures is sufficient. The greatest share of success will be attained by him who neglects nothing. I have spoken chiefly of electricity because it is the least known, the least used, perhaps in this country, the most despised of therapeutic measures, whereas in regard to disease of the peripheral nerves it also is the most useful, the most directly applicable, the most indispensable of all. Bearing in mind, however, the accessibility of the part affected, its remarkable vitality, and the readiness of its response to changes in the environment, I find no occasion to dwell upon the multiplicity of resource that is possible in its treatment.

GENERAL OBSERVATIONS ON THE CONDITION KNOWN AS THE "TYPHOID STATE," WITH REFERENCE TO EXAMPLES IN MEDICAL AND SURGICAL PRACTICE.

BY NORMAN HAY FORBES, F.R.C.S.EDIN.,
FORMERLY ON THE MEDICAL STAFF OF H.M. ARMY; MEDICAL OFFICER, TUNBRIDGE WELLS DISPENSARY.

"Τὸ ὄνομα μηδὲν τῷ πράγματι ποιεῖ."—XENOPHON.

I.—MEDICAL.

IN attempting to arrange a few, fragmentary notes in connexion with my subject I am reminded of a remark which that astute essayist Sterne once penned: "When a man," said he, "sits down to write a history, though it be

Digitized by Google

but the history of Jack Hickathrift, he knows no more than his heels what lets he is to meet with in his way." Despite the lets, and irrespective of many imperfections, I shall endeavour to deal *seriatim* (1) with the meaning of the term "typhoid state" and what it exactly comprises; (2) with the circumstances under which the condition arises and its general causation; (3) with its clinical phenomena, its symptoms, and their course; and, lastly (4), with its prognosis and treatment.

1. *Definition and meaning of the term.*—The terms "typhoid state," "état typhoïde," "état adynamic," "typhoid condition," and "typhoid symptoms" so frequently mentioned in standard works on medicine and surgery and in the clinical reports of cases and patients in whom the condition supervenes during the course of some more or less serious illness, are not infrequently seen both in the wards of a general hospital and in private practice, so that any apology for reintroducing the subject need hardly be tendered (*vide* Murchison, Milner Fothergill, &c.). By the term "typhoid state" we understand a well-marked group or series of symptoms arising during the course of any disease in which "fever" (pyrexia), from whatever cause, is the essential feature of that morbid condition, and when that pyrexia is either excessive or long-continued, or both, the train of symptoms being "centralised" in the generic term "typhoid," which is in itself, without doubt, somewhat loose and indefinite, pathologically more or less inaccurate, and, lastly, not strictly logical. For in its history and etymology the word "typhoid"—derived from the Greek τῦφος (smoke or vapour) and εἶδος (resemblance of form, or likeness)—conveys the general idea that the condition is like or resembling typhoid fever, like the stupor seen in typhoid fever—and, that being so, it does not tell us anything precise regarding its true and exact nature—nothing essential about the condition itself, but merely that it is like, or has the appearance of something else, and so this lax term has imperceptibly come to convey in a somewhat vague and non-scientific manner the general idea that the condition is, comparatively speaking, identical with a condition first observed in typhus and in typhoid fevers. Briefly, the object of this paper is to endeavour to generalise the views and opinions regarding the so-called "typhoid state," and at the same time to state clearly and concisely its true pathological and clinical import in disease, and to summarise its characteristic features. In this country the late Dr. Charles Murchison and the late Dr. Milner Fothergill have contributed papers on this subject, while many interesting references are to be found in foreign literature: e.g., (1) in "De l'État typhoïde considéré dans les différentes Maladies";[1] in (2) "Typhoid Termination of Acute Inflammation";[2] and (3) in "De l'Autotyphisation par Excès de Fatigue et des Maladies Typhiques en général."[3] Relating to this subject, the following passage occurs in Finlayson's "Clinical Manual":[4] "It should be particularly remarked as necessary for the reconciliation of old and new terms, that the word 'typhoid' is not used here in the special and limited sense given to it by Louis and the French school of the present century, as a designation of enteric fever, but in that larger and more general meaning which it had from at least the time of Galen of 'typhus-like' (τῦφος εἶδος). Typhus, and most of its derivatives, including typhomania, are Hippocratic words used in a figurative sense from 'τῦφος' 'smoke,' as indicating the stupor which attends the graver kinds of fever, and, in the case of typhomania, the combination of stupor with restless delirium—exactly the functional contrast referred to above. The etymological facts are interesting, as showing how, even in the most remote period to which the literature of medicine extends, clinical phenomena which only receive their physiological interpretation from modern science, were nevertheless sometimes very exactly noted."

2. *Causation and circumstances under which the condition arises.*—The causes which induce the appearance and development of the "typhoid state" may generally be arranged under three main heads. In the first place, in both medical and surgical cases a most important and primary cause lies in the toxic and noxious influence that a high internal temperature has upon the tissue elements of the central nervous system and more especially upon those parts of the medulla in which are located the "respiratory" and "cardiac" centres, as well as the so-called "thermo-genetic" "centre." Secondly, another important etiological factor is the direct and cogent effect that this same high temperature both of blood and tissues has upon the parenchyma of the glandular organs, the liver, kidneys, and spleen, lessening elimination and blood elaboration, and acting injuriously upon the muscular fibre both of the heart and voluntary muscles. The third head in the causation of the condition in question lies in certain ill-understood chemical changes in the composition of the blood, and the effect that that chemically-altered blood has upon the bloodvessels and tissues generally of the body. This latter problem is a difficult one to solve, a "quæstio vexata," owing to the fact that our knowledge of the physiological chemistry of the blood (cf. writings of Halliburton, Hunter, Wooldridge, Crookshank, &c.), and of the action of toxic albumoses (Martin), ptomaines, and leucomaines, coupled with putrefaction products in the blood is more or less in a preliminary and transitional stage, and consequently limited, dimly lighted, and admittedly imperfect. Thus, to summarise this last factor, we have—(1) the absorption of the effete products of chemical combustion in the body; (2) the toxic effects of pathogenic, "infective," micro-organisms in the blood; and (3) the consequent alteration in the forces of the circulation, and variations in blood-pressure and nerve-stimulus.

The diseases in which the "typhoid state" most frequently occurs are for the most part as follows:—(1) typhus fever (Rouillion), and the "typhus traumatique" of Ollivier; (2) yellow fever, "bilious typhoid" (Fagge); (3) enteric fever (the term "typhoid fever" should be discontinued); (4) certain "pernicious," malarial fevers; (5) the "malignant" type of scarlet fever; (6) variola (Hilton Fagge), especially in the third week; (7) in the first stage of the plague, "after the appearance of intense pyrexia, and subsequent violent delirium";[5] (8) in cholera-typhoid, and in cholerine (Hilton Fagge); (9) in diphtheria, where the characters of an "infective" fever with febrile albuminuria and other "typhoid" symptoms are evident; (10) in "adynamic" remittent fever, and in the so-called "typho-malarial fever" of the United States; (11) in "malignant" and "intestinal" anthrax—in this condition, however, the temperature is not always high; (12) in "infectious pneumonia" of an epidemic nature, and "croupous" or "fibrinous" in type (Whitelegge)—this occurs both in fatal and in non-fatal cases which are severe and protracted; (13) in chronic starvation and general wasting (Whitelegge); (14) in phlebitis (Hodgson, Breschet, Blaudin), and in "la phlébite utérine" (phlegmasia dolens); and (15) in experimental injection of septic substances into the veins (Gaspard, Laurent, and Dupuis).

3. *Clinical phenomena, symptoms, and general course of the "typhoid state."*—Passing from a study of the etiology of this condition, to view the symptoms noted in cases under observation, the fact must be borne in mind that there are several phases of this "state" distinctly different in their nature but that in all cases there is an apparent similarity in the grouping sequence and arrangement of the symptoms. It will be convenient to classify those signs under the systems to which they naturally refer—as, for instance: (1) those symptoms directly referable to the nervous system, these being the most important and, as a rule, the most prominent; (2) those both primarily and indirectly referable to the circulatory system; and (3) those referable to the respiratory, digestive, and excretory systems. The phenomena referable to the nervous system constitute the major and more serious aspect of this condition, and in noticing them somewhat in detail it must be remembered that they are essentially characteristic evidences of a "diseased" and profoundly "depressed" condition of the higher nervous centres. Perhaps the most striking feature is the absolute depression of the nervous force and vital energy (adynamia and the diminution of the physiological activity and cell function of the brain). The patient is seen lying on his back, prostrate, listless, and quite indifferent to his surroundings. There is a low, somnolent, muttering delirium, gradually shading into a dull, comatose stupor, of heavy and "dusky" aspect, little or no real sleep (coma-vigil), associated at times with derangement of the senses, and hallucinations of sight and hearing. The power of the mental faculties is impaired—a dull and clouded intellect, a mind wandering strangely. The delirium may at one time be acute, violent, and noisy, an exacerbation from

the more frequent low, muttering, and lethargic type. Sometimes muscular (fibrillar) tremor occurs, occasionally subsultus tendinum, carphology, and general convulsions. The urine and fæces are passed involuntarily, though in some cases retention and suppression of urine have been well marked symptoms. The fæcal evacuations are usually semi-solid, of a black colour and grumous appearance, and have a highly offensive odour. The urine passed in small quantities often contains albumen, frequently lithates in excess, and a diminution in the chlorides. The chief points observable with reference to the circulation are, that the pulse is quick, soft, small, irregular, and easily compressed, occasionally dicrotous, indicating a marked degree of diminished intra-arterial tension. The heart's impulse is weakened, sometimes scarcely perceptible, and there is almost a complete absence of the first sound at the apex. No distinctive cardiac bruit is audible. Turning to the digestive system the tongue is found to be dry, of a dark-brown or almost black colour, incrustated with thick, dark, russet-brown fur, tremulous, with an abundance of sordes on the lips and teeth. Hiccough is also present, at times frequently distressing, the breath having a peculiar heavy, offensive odour. The skin is in some cases dry and hot, with a surface temperature of 102° to 104° F.; in others it is bathed with a cold, clammy sweat, the temperature then being subnormal. There is also impairment of the general tactile sensibility of the skin together with taches bleuâtres, and extreme muscular weakness. It would appear that there are at least two distinct types of the "typhoid state," the one characterised by a marked elevation of temperature—pyrexia in a high degree; the other in which a subnormal temperature obtains, an apyrexial type. Thus in the "state" we must admit three main factors for consideration: (1) the existence of pyrexia, whether of a "sthenic" or "asthenic" type, more frequently the latter; (2) the essentially important part played by the nervous system in tending to induce such a "condition"; and (3) in some cases (surgical) the possibility of auto-inoculation and septic infection,[6] together with the absorption of the waste products of decomposition. In the more dependent parts of the body ecchymoses appear—especially over parts usually exposed to pressure; there is a general lividity of the limbs, and petechiæ are scattered here and there over their surfaces. The respiration is, as a rule, hurried and shallow, sometimes becoming stertorous. The physical signs of hypostatic congestion of both pulmonary bases are well marked in many cases. It would be highly advantageous if one could have the opportunity of making a detailed post-mortem examination, with a microscopic examination of the tissues, as well as of the blood and other fluids both during life and after death.

4. *Prognosis and treatment.*—In determining the prognosis of the "typhoid condition" difficulty and responsibility beset the practitioner, and, as in other morbid conditions, an expression of opinion must be guarded and based on a sound and broad consideration and estimate of the chief symptoms. The most important prognostic indications seem to lie in: (1) the effect produced upon the higher nerve centres; (2) the condition of the heart and bloodvessels; (3) the condition of the kidneys and the result of a careful urinary analysis with special reference to the presence or absence of albumen or sugar; and (4) the condition of the lungs. In the treatment of the "typhoid state" the *cause* of that condition must be the guiding principle, and in every instance the only correct and rational method of treatment will be based on a thorough knowledge of that cause. In the light of "general principles of treatment" attention must specially be directed to the nervous phenomena and the condition of the heart and circulation generally, not omitting such good and careful nursing as will husband the patient's strength as much as possible and tide him over a critical period. The administration of such drugs as the perchloride of iron in combination with the hydrochlorate of quinine and liquor strychniæ every four hours is clearly indicated and is most likely to be attended with an improvement in the patient's condition; benefit is also derived from hypodermic injections of ether, strychnia ($\frac{1}{70}$ gr.), morphia ($\frac{1}{6}$ gr.), and nitroglycerine ($\frac{1}{100}$ gr.), when the "exhaustion" is very pronounced. In order to maintain the force of the cardiac systole, and the tone of the cardiac muscle, such tonics as digitalis, convallaria, strophanthus, spartein, and cactus grandiflorus are of the utmost service; the last-named drug I have found very useful in five- to ten-minim doses of the liquid extract combined with quinine and opium. The free but judiciously guarded use of alcohol in the form of brandy, brandy and egg-and-milk, and brandy and meat-juice, is of the utmost importance. The alcohol must be administered with other liquid food at regular intervals, and the quantity determined by the condition of the pulse and temperature. Rectal feeding must also be resorted to in order to supplement the ordinary method and to assist in supporting the patient. Local applications, such as tepid sponging with vinegar and water, the wet pack to the head and limbs, also mustard-leaves or poultices to the præcordia, and hot bottles to the sides and feet, are of considerable value. Attention to details of treatment, careful investigation into the condition of the excretory and other organs, and minutiæ of thoughtful and intelligent nursing will all materially assist in bringing about a satisfactory and successful issue.

II.—SURGICAL.

In the domain of surgery, the examples of the "typhoid condition" can be for the most part roughly divided into those occurring in (1) any acute inflammatory condition associated with marked pyrexia and profound disturbance of the nervous system, and (2) those occurring in long-standing and in some of the more chronic forms of constitutional disease associated with the sudden onset of acute and consequently grave symptoms, the result in the main of either absorption of the organised chemical products of decomposition (septicæmia), or of chronic suppuration, or of a series of symptoms directly referable to the nervous system "broken down" and exhausted by prolonged suffering. I will specify somewhat in detail. Under the secondary constitutional effects of injuries or of operations and of some diseases there occurs that most important clinical feature known as "surgical" or "traumatic" fever, which implies a general disturbance of vital processes and functions as well as of the thermo-genetic equilibrium. In those cases in which this fever assumes what is termed an "asthenic" or "adynamic" type, there is afforded a typically developed example of the "typhoid state," a condition in which the terms "typhoid" and "asthenic" are almost synonymous. This form of "asthenic" pyrexia is seen in patients whose general health, constitution, and vital powers have been severely undermined by excesses of various kinds, more especially by alcoholism, by privations, and by any or all of those depressing causes in any disease acting consecutively. In this condition the temperature is not *per se* a cardinal feature, as it may be high or comparatively low, the chief points being the complete exhaustion of the nervous centres, a feeble, failing, irregular pulse, shallow respiration, extreme muscular weakness, and a dry, brown, tremulous tongue. Another instructive instance of "typhoid" symptoms setting in occurs in one or other of the various forms of septicæmia, whether this be the outcome of septic infection, septic "intoxication," or embolic pyæmia (which is septicæmia *plus* metastases). In this septicæmic condition all the leading characteristics of the "state" are found—low, muttering delirium, flickering pulse, stupor, &c. It is a well-known fact that in all "infective" or "septic" inflammatory processes the symptoms frequently and almost imperceptibly merge into an "asthenic" type, this general asthenia of motor, sensory, and psychical power thus producing a "typhoid" condition. In another group of cases, such as those of chronic catarrh of the bladder (chronic cystitis), with thick, copious, muco-purulent secretion, the patient sometimes sinks, without strength and "worn out," the closing scene being characterised by a "typhoid" condition. In such an example, in all probability, two distinct factors are at work in bringing about a fatal issue—viz., (1) the constant exhaustive drain effected by long-continued reflex irritation on the nervous system; and (2) the chemical changes occurring in the urine, in the blood, and in the exudative discharge from the vesical mucous membrane, and in the combined effect on the excretory organs, and indirectly on the general nutrition of the body. This condition is also observed in the third stage, that of pyrexia with exhaustion, in dissection or in post-mortem wounds (*piqûres anatomiques*), where the subtle and rapid absorption of the necrotic virus, and its still more alarmingly rapid multiplication and chemically toxic power within the system, have the baneful effect of establishing an intense depression and disturbance of the functions and influence of the nerve centres, ending in a destruction of

Digitized by Google

their vital force and power. Cases of diffuse cellulitis can be recalled—the "diffuse phlegmon" of Dupuytren—where, in a previously debilitated system, severe constitutional disturbance supervenes, and a train of "typhoid" symptoms sets in. This is also the case in examples of acute spreading gangrene, a condition in some aspects allied to chronic septicæmia, in which the absorption of the chemical products of disintegration and putrefaction has from first to last a toxic and seriously injurious effect. The condition has also been noticed in wide-spread burns of the fourth and fifth degrees. Another instance of the "typhoid" phenomena occurs during an attack of "delirium tremens," the result of hard drinking, when marked signs of exhaustion of the nervous system set in with failure of functional power, and again in those cases of "nervous traumatic delirium" which not infrequently arise in patients with an "irritable" and somewhat unstable nervous system, or in those who have suffered from prolonged mental anxiety and the enervating effect of worry and over-strain. If the patient be the subject of an almost impermeable organic stricture, and if unrelieved retention exist, and if, in consequence of the rupture of the dilated portion of the urethra which is immediately behind the seat of such a stricture, extravasation of urine takes place, the united effects of such a condition, both local and general, give rise, on the one hand, to the most deleterious consequences to the tissues themselves, and, on the other, severe constitutional disturbance; "typhoid" symptoms rapidly supervene, in which muttering, quasi-insensible delirium, a small and rapid pulse, and dry, brown, and cracked tongue, form the most prominent features. Clinically allied to the foregoing condition, and in natural sequence, is the disease described under the term "acute, diffuse, interstitial, suppurative nephritis," associated with multiple scattered abscesses ("surgical kidney") in which the patient sooner or later sinks into a heavy, drowsy state, "typhoid"-like in character, and succumbs within a comparatively short time from poisoning by absorption of septic matter and waste products, a condition of uræmia, and closely resembling chronic pyæmia or septicæmia. Lastly, one observes the development of "typhoid" symptoms in cases of acute traumatic meningitis and encephalitis, complications of some injury inflicted on the skull and the structures contained within it. In these cases, with an open wound of the head, infection readily and often insidiously takes place unless more than ordinary care is exercised to prevent the establishment of a condition of sepsis. If, however, septic meningitis has taken place there is a speedy exacerbation of the general symptoms, especially the temperature, which mounts up to 104° F., concurrently with restlessness and delirium, which, if symptoms of compression coexist, passes into that drowsy, stupefied type, the breathing becoming stertorous, the pulse feeble and failing, and the patient succumbs in an exhausted condition from the dual effect of failure of the nervous system and compression. In the intra-meningeal form of intra-cranial suppuration which is occasionally associated with pyæmia "typhoid" phenomena appear towards the close of the case. In the days before attention was definitely directed to hygienic conditions in relation to surgical procedures cases not infrequently occurred where anæmic, cachectic, and debilitated patients, crowded together in a small, ill-ventilated ward, suffered from languor, headache, "continued fever," and similar symptoms indiscriminately passing into an "adynamic" or "typhoid" condition,[7] which was in part due to the poisonous effects of an excess of carbon dioxide, gases of decomposition, and organic impurities in the air of the ward, and in part to the absence of sufficient air space per bed. Another important consideration in connexion with the development of the "typhoid state" during the course of any disease lies in the fact that in overcrowding and the continued inhalation of a vitiated atmosphere there is a marked prevalence of diseases of the respiratory tract, such as phthisis, pneumonia, and bronchitis, all of which, under the above-mentioned conditions, have a tendency to assume an "adynamic" type closely allied to the "typhoid state." Of the twenty-three survivors of the Black Hole of Calcutta many suffered from a condition which is designated under the term "putrid fever," probably allied to typhus fever,[8] in which "typhoid" symptoms were well marked. An example of the supervention of such symptoms is also met with in animals in severe cases of "foot-and-mouth" disease, in which there is much fever, prostration, and thirst, these symptoms being the more pronounced in sucking animals.[9] Writing on the "typhoid condition," Tweedie states that "it is announced by the decline of the previous more acute symptoms: by the pulse becoming more rapid and soft; the tongue dry and brown, tremulous, and protruded with difficulty; by the incrustration of the teeth with sordes; by the increasing intellectual disorder, indicated by the more constant low, muttering delirium, and the greater insensibility and deafness; and by the condition of the muscular system evinced by muscular tremor and subsultus tendinum, and in some cases irregularity or intermission of the pulse; by the patient lying sunk on his back or sliding to the foot of the bed, the muscles being unable to support the body even in the horizontal posture." Milner Fothergill reviewed this subject under the following considerations:—(1) the association of high temperature with its effect on the entire muscular system—this point has also been emphasised by C. B. Radcliffe, Wunderlich, and Bennett Dowler of New Orleans; (2) the general wasting of the muscles in fever; (3) the marked sense of prostration (*debilitas febrilis*); (4) the excess of urea excreted in the urine, there being a definite relation between temperature and amount of urea (in 'typhoid fever' about 1065 grains of urea are excreted in twenty-four hours, the normal being 400 grains); and (5) the pathological condition of the muscular structures before and after death. He also considers that this condition is due to an increased metamorphosis of blood and tissues with subsequent rapid wasting of the latter ("histolysis"), and that it is a common and necessary result of fever. He insists on the importance of "muscular prostration"—the patient being often found lying on his back in the middle of the bed, having gradually slipped down—as a characteristic clinical sign, and notes that "muscular weariness" is one of the earliest symptoms. The remark of Da Costa that "no blunder is more common than to misconstrue into typhoid fever a typhoid condition of the system" is not without its weight and value in reference to diagnosis.

III.—CONCLUSION.

In concluding these incomplete remarks on the "typhoid state" I regret that I am unable at the present to furnish further details as to its pathology, and as to the temperature or the condition of the circulation as shown by sphygmographic tracings. I have not yet been able to find an adequate reply to the query, Does the "typhoid" condition occur more frequently among persons of a highly nervous temperament or of a hereditarily unstable nervous system? I have not been able to discover any examples of this condition in cases of malignant disease, whether sarcoma or carcinoma.

In asking the indulgence of the readers of THE LANCET I am reminded of Boileau's lines:—

> "Hâtez-vous lentement; et, sans perdre courage,
> Vingt fois sur le métier remettez votre ouvrage:
> Polissez-le sans cesse et le repolissez;
> Ajoutez quelquefois, et souvent effacez."

Tunbridge Wells.

ON THE

TREATMENT OF ACUTE RHEUMATIC ENDOCARDITIS.

BY RICHARD CATON, M.D. EDIN., F.R.C.P. LOND.,
HONORARY PHYSICIAN, LIVERPOOL ROYAL INFIRMARY.

IN the year 1881 I commenced a definite inquiry, which I have pursued steadily for fourteen years so far as cases suited for the purpose came under my observation, on the course and treatment of the acute endocarditis of rheumatism, and I now propose briefly to state its results.

Gravity of cardiac rheumatism.—Numerous cases of acute rheumatism necessarily come under the care of every hospital physician—I have treated about 320 cases of acute and subacute rheumatism during the fourteen years in question. While speedy cure of the rheumatism itself usually follows, a proportion of these cases—perhaps 1 in 3 or 4—suffer

Digitized by Google

cardiac complication, and the physician has the pain of seeing the patient leave the hospital bearing the seeds of a malady which is certain to cause suffering and shorten life. Perhaps the physician follows the whole career of such a case extending over some years. A vigorous man comes to him suffering from acute rheumatism, but with a sound heart; endocarditis affecting the mitral valve occurs and persists; the rheumatism subsides, the patient returns home thinking himself well, but on exertion suffers from an unaccustomed shortness of breath; bronchitis, increased difficulty of breathing, inability to follow his occupation—if it be a laborious one—and dropsy follow; dilatation of the right ventricle, and tricuspid disease may set in and death closes the scene. Many of us have seen cases like this, and have felt their extreme sadness.

Objects of the inquiry.—Feeling the importance of doing what little was in my power to further any inquiry which might mitigate the frequency of heart disease, I set myself during the last fourteen years to try to obtain information on two points—viz., (1) as to how the occurrence of endocarditis may be prevented during acute rheumatism; and (2) whether or not, when it does occur, any treatment during the incipient stage would favour recovery. When the disease is fully established of course there can be little hope of benefit. I had first to acquaint myself with the experience of former writers in our own country, in Europe, and in America. That of the earlier authors I found of less value on account of their imperfect diagnosis; and also their treatment, on account of its severity, did not commend itself to me. The opinion of more modern writers was highly conflicting. Some considered all measures having in view either prevention or cure practically useless. The weighty names of Niemeyer and of Osler were among these. It was encouraging to find Sibson and others pointing out the value of absolute and protracted rest, both as a prophylactic and as an aid in the cure of incipient endocarditis. Various writers described the occasional spontaneous disappearance of bruits in acute rheumatism. This, I think, there can be no doubt of: I have myself seen it happen twice. The general opinion was that a bruit when once established remains in the large majority of cases, and is followed by permanent heart disease. Many forms of treatment were suggested. The older writers advise bleeding and mercurial salivation, the local employment of dry and wet cupping, leeches, blisters, mustard plasters, iodine, ice-bags, poultices, the actual cautery, the internal administration of potassium or sodium iodide, digitalis, aconite, mercury, &c.

Bad results of expectant treatment.—Meantime I proceeded to observe a number of cases, merely treating the rheumatism by salicylates and keeping the patient in bed under generally favourable conditions, but doing nothing of a special kind for the endocarditis. In other cases I experimented with some of the milder among the agents I have referred to. Up to the end of December, 1885, the results obtained from merely treating the rheumatism and doing nothing for the endocarditis, also from partial blistering or the use of leeches or poultices, were not favourable; of fourteen cases one lost the bruit spontaneously, although no treatment was employed; a second lost it after repeated blistering and the use of potassium iodide; and the remaining twelve went out with a bruit which I fear has been permanent in each case, and has probably terminated in death in many instances before now. The experience of these four years disposed me to adopt some definite method. Adopting no treatment had led to unfavourable results alike during this period and during previous years.

Method of treatment selected.—Guided by the physiological facts to be stated later in this paper, it seemed to me that the use of a succession of small blisters along the course of the fourth, fifth, and sixth intercostal nerves, together with the internal use of potassium or sodium iodide not only gave as much promise as any other method, but tended but little to disturb or to weaken the patient. I had, moreover, had one successful case already, Case 12 (see Abstract), in which an aortic bruit disappeared; so I proceeded to treat almost all subsequent cases in this way, enjoining also a prolonged rest in bed.

Before detailing the results I ought to say something about (1) the general treatment of these cases of acute rheumatism; (2) about the efforts made to prevent cardiac disease; and (3) about the evidence I relied upon as indicating the presence of genuine endocarditis in the cases on the list which I subjoin.

1. *General treatment of rheumatic cases.*—The patients are kept in bed; I prohibit as far as possible all exertion or exposure. No getting out of bed is allowed, and to prevent chills a long flannel nightshirt is worn, a stock of these garments being kept on purpose for rheumatic cases in my wards. Thus the profuse perspiration incident to the disease is not likely to be checked. A light milk diet is given. Gentle cholagogues are administered and salicylates are given in such measure as the disease seems to demand. If the pain fails to yield in any joint I immediately apply small blisters followed by poultices, a method which rarely fails to give great relief, as I can testify from the experience of hundreds of patients. Hyperpyrexia or any special symptom receives appropriate treatment. The patient is kept in bed and on a light diet for a considerable time after the disappearance of pain.

2. *Efforts to prevent cardiac complication.*—There seems to be strong ground for believing that perfect quiet and rest and avoidance of chills during acute rheumatism lessens the liability to cardiac complication. Cold to the surface undoubtedly increases the inflammation of synovial membranes; rheumatic inflammation of the endocardium is similar in kind and is likely to be affected similarly. My own experience certainly is in favour of this opinion. In what proportion of cases is the heart affected? There is much divergence of opinion as to the proportion of cases in which the heart is attacked. Codet, the French writer, puts it down at 81 per cent., Picot at 78 per cent., Mansir and Shadwell's list from Guy's Hospital Reports gives over 50 per cent. The lowest average I read of is 25 per cent. During the period my list of cases covers I have had about 320 cases of febrile rheumatism, but in many of them the fever was slight and temporary. My proportion is under 20 per cent. Probably the great discrepancy in percentages is due to different conceptions of the meaning of the term "acute rheumatism." If it be restricted to the highly febrile type the high estimates (60, 70, 80 per cent.) I have quoted will probably be correct. Though, according to my own experience, endocarditis is not confined to pyrexial cases, it is certainly more frequent in them, and I think I may consider my proportion of cases of rheumatism with cardiac complication to have been comparatively small.

3. *Were my cases examples of genuine endocarditis?*—I should like to say that of course cardiac murmurs are of very different values. The bruit of anæmia, for instance, heard chiefly about the pulmonary area, and the bruit of muscular weakness which is sometimes met with in fevers and other conditions of exhaustion, are not to be mistaken for signs of endocarditis. The former occurs sometimes in acute rheumatism, but only in the later stages. The murmur at the pulmonary cartilage in Case 41 (see Abstract) was probably of this order. Also the bruit due to muscular impairment, if it occurs at all in rheumatism, happens at a late period, when the patient is enfeebled by a lengthy illness. I have always been on my guard against mistaking either of these forms of bruit for that occasioned by endocarditis. The great majority of the cases in the list are those of commencing mitral disease. The aortic valves were affected in five cases, and in seven pericarditis occurred. I make it a rule to examine the heart of every rheumatic patient daily, so as to be on the lookout for any commencing mischief.

Period at which the heart is affected.—In a few cases endocarditis seems to occur coincidently with the first rise of temperature and the joint affection. More often it happens during the first ten days; sometimes it is later when the temperature has fallen and pain gone and the patient thinks himself getting well. Sometimes it occurs during a relapse of the rheumatism, as in Case 18. The patient had been going on well for a week with normal temperature, when suddenly, on March 9th, the temperature rose and endocarditis became apparent. If a bruit has disappeared it is apt to recur during a relapse of the rheumatism, as in Cases 44 and 48. As to symptoms, there are sometimes præcordial discomfort and further rise of temperature, but generally, in my opinion, no special symptom has attracted the patient's attention when an endocarditis has first become perceptible to the physician. In pericarditis symptoms are more common. The following has been my experience of the first signs of endocarditis. Suppose a case of mitral regurgitation. The patient has been admitted with a heart the sounds of which were normal excepting as regards rapidity of beat. One notices a change in the character of the first sound—what the French writers call "assourdissement"—a loss of clearness and sharpness in the tone. The note is dull

Summary.

Of 39 cases treated by repeated blistering over heart and administration of iodides (average stay in hospital, 41 days), 29 left hospital without a bruit; 7 left with a bruit; and 3 were uncertain—they probably had a bruit. Of 13 cases not treated, or treated otherwise (average stay in hospital, 25 days), 1 left hospital without a bruit, and 12 with a bruit.

and woolly, so to speak; it becomes prolonged, and this dull, prolonged sound by degrees changes into an undoubted bruit. Many and many a time have I noted these changes, and foretold them from the time when the first dulness of tone was observed. The bruit is best heard about the apex, but is audible in the axilla; it is usually systolic, occasionally presystolic, and sometimes it is both. Frequently it is accompanied by accentuation of the second sound in the pulmonary area.

Details of treatment of incipient endocarditis.—As soon as the bruit is perceptible, or even prior to that, during the preliminary stage of "woolliness" I at once give potassium or sodium iodide in ten-grain doses thrice daily in addition to the salicylates, and apply near the apex a blister about the size of half-a-crown; as soon as the irritation of this blister is subsiding I apply a second close to it, then a third and so on, keeping the patient meantime as quiet as possible, strictly forbidding exertion, exposure, or too much nitrogenous food. I have scarcely ever known the patient to complain of the blisters, which practically occasion little or no discomfort. The heart should be examined daily. Frequently in a week or in ten days' time I have had the satisfaction of noting a gradual subsidence of the bruit; day by day it becomes less clear and distinct, until at length it is found to be only occasional, and at last to be entirely absent. Sometimes several weeks elapse before this desirable change is accomplished. I think the prolonged rest in bed has an important share in this good result. It will be noted that the thirty-nine cases which I treated on the above principle were, on the average, forty days in hospital, and were confined to bed for thirty-five or thirty-six days. When the bruit has gone, I have, when possible, kept the patient under observation for awhile. Sometimes this is not practicable, but I have often for many weeks noted the condition of the heart and found it perfectly normal. In some instances I have done this for two or more years.

Excellent results obtained.—It will be observed from my list that in the thirteen cases which were either not treated at all or imperfectly treated by blistering, poulticing, leeching, &c., with an average residence in hospital of twenty-eight days, the result was that twelve left hospital with a bruit which I fear they retained throughout life. One case, however, lost his bruit spontaneously. But of the 39 cases treated by prolonged rest, repeated blistering, and the administration of iodides, 29 left hospital with normal heart sounds, in 3 the result was doubtful, and 7 left with a bruit. I must confess that this series of twenty-nine patients in whom distinctly marked bruits had been heard, but who left the hospital with normal heart sounds, constituted a better result than I had ever ventured to hope for. It is, in fact, so good a result that I do not expect that the readers of this paper will altogether accept it. Many will believe that mistake or error has crept in somehow. To the best of my knowledge and belief, what I have stated is accurate. The cases were not examined and recorded by myself alone, but by registrars, house physicians, and clinical clerks.

Theory of the treatment.—I claim for this method that it is essentially a reasonable one on the following grounds. So-called "counter-irritation" has fallen much out of vogue in the profession, partly because the old theories on which it was formerly supported are felt to be untenable. We cannot believe that a poultice or blister draws blood from, or acts directly in any manner upon, an organ in the thorax or abdomen, but it by no means follows that the practice is bad because the former theory was unsound. Such treatment has been partially abandoned also because our predecessors carried it out to excess so as to cause pain and to enfeeble the patient. If we apply a small blister or a poultice to the skin of the thorax or abdomen I believe its effect on the organs situated at some distance beneath is solely an effect transmitted through the nervous system and reflected from the nerve centres in the spinal cord and sympathetic system. The nervous system may be summarised as a series of segments arranged in a line corresponding to the various somites of the body; each nerve segment governs to some extent the nutrition of its own somite, alike as regards epi-, meso-, and hypo-blastic structures. If a cutaneous nerve is stimulated the nerve cells in the spinal and sympathetic centres are influenced, and the impression is reflected to the visceral branches. It may be said that this is mere theory, but it is a theory which satisfactorily explains many familiar facts—e.g., it explains the fact that a slight chilling of the skin of the thorax may cause pneumonia or bronchitis, and that a splash of cold water will excite respiration in the infant or set a-going the action of the heart in a faint. I may add that I think I proved this theory in a paper read before the Physiological Society at Oxford a few years ago by demonstrating that stimulation of the surface skin altered the diameter of the arterioles in the lung and caused variation in the electrical condition (as manifested by the galvanometer) of thoracic and abdominal organs. It is quite clear that stimulation of the skin of the abdomen by heat, by chemical irritation, by faradaism, or by mechanical irritation produces instantly a variation in the electrical potential. This, however, is so extensive and complex a subject and occupied so many months of hard work in the laboratory that I cannot hope to make it clear in the space of a few lines. Turning to more familiar evidence, few persons, I think, will deny the soothing effect of a poultice in a case of bronchitis, nor, I think, can any explain that effect satisfactorily in any other manner than that I have just stated. When that form of impaired functional activity is occurring in the tissues of the heart which is called "rheumatic endocarditis," a stimulus is applied to the nerve centres, and the trophic nerves of the heart help nature to overcome the defective action. That is the theory on which this treatment by blistering is based. I believe that the assisted natural powers succeed where, if unstimulated, they would fail.

I should like to say here that after twenty-five years' experience of counter-irritation in many forms, carried out in view of the theory I have stated, I think it is one of our most valuable therapeutical expedients for the relief of pain, for lessening inflammatory action, and for the stimulation of restorative processes. A very limited irritation of cutaneous nerves will suffice; I never use large blisters—generally they are smaller than a florin; small vesications give great relief and cause practically no suffering and no loss of strength. As to the sodium or potassium iodide, it is given on account of its value in absorbing inflammatory products of low vitality. I am anxious to know what the experience of others has been in regard to the very grave disease in question, and to hear of alternative or superior plans of treatment. In conclusion, the one thing I am specially anxious about is that members of the profession who have the opportunity of observing cases of acute endocarditis should give this method a fair trial during the early stage of the malady. If they do, I think they will not be disappointed.

Liverpool.

INFECTIOUS SORE THROATS.[1]

BY J. C. THRESH, M.B. AND CH.B. VICT.,
MEDICAL OFFICER OF HEALTH FOR CHELMSFORD, ETC.

THE importance of obtaining early information of outbreaks of infectious disease led me some three years ago to issue a circular letter to all the school managers in my districts asking them to instruct their head master or mistress to give me the earliest possible intimation of the presence amongst the children attending school of any affection which appeared to be infectious, and I also drew attention to the fact that sore throat, especially if associated with headache or sickness, was one of the earliest symptoms of certain infectious diseases. The result of the above procedure has been that many epidemics in which the most constantly marked symptom was sore throat have been brought under my notice which could neither be referred to diphtheria nor to scarlet fever. The following are examples.

In February, 1893, I received a note from the schoolmaster of an isolated parish saying that he was afraid that diphtheria had broken out in the school. I found several children were then in school who had been absent during the previous week for three or four days. They had suffered from headache, more or less marked, a little feverishness, and sore throat. In a very few days they were sufficiently well to return to school. Examination of the tonsils simply showed that they were enlarged, pale, and somewhat flabby. I visited several of the absentees and found in most cases they had suffered from a little headache and chilliness. The tonsils were enlarged, not abnormally red, but the mucous membrane round the apertures of the follicles was distinctly infiltrated, slightly thickened, greyish, and opaque. Exactly the same

[1] Paper read at a meeting of the Home Counties Branch of the Medical Officers of Health Society, Feb. 7th, 1895.

condition had at this time led at least two practitioners in my district to notify such cases as diphtheria. Two patients in the particular outbreak referred to suffered more severely, both bleeding freely from the nose. One had a temperature of 104° F. for two days, probably due to tonsillitis, which was followed by suppuration. The disease was evidently infectious, two and three children in one house being attacked. A few adults also suffered, and both the severe cases mentioned were of adults. I concluded that this was a form of influenza, since a few typical cases of that disease were met with, and usually in houses in which others were suffering from sore-throat. In various other parishes about this time I met with similar cases, some of which, as just remarked, were diagnosed as diphtheria. Beyond the circular patches of infiltrated mucous membrane round the apertures of the crypts of the tonsils there was nothing to indicate diphtheria. At a later date I examined such a throat bacteriologically, but obtained no diphtheria bacilli. In May a similar epidemic occurred in another parish many miles distant, but a large proportion of the patients suffered from epistaxis, and there were no typical cases of influenza in the same houses. In none of the above cases was any rash observed. In October of the same year I was asked to visit another parish in which the school attendance was suffering from absence of children on account of sore throats. I found that most of the children affected had been out in the fields picking acorns in the damp grass. The children appeared at first to have taken cold, then the throat became very sore, and the submaxillary glands at one or both sides enlarged. The tonsils resembled those just described, but in one case the mucous membrane of the pharynx was affected, and I seriously suspected diphtheria for a time. Herpes on the lips was met with in several instances. This little outbreak, if we may so call it, seemed to me to be due to "catching cold," whatever that may mean, and that the prevalence was due not to any infective quality, but merely to the fact that a considerable number of children had been occupied out of school hours in gathering acorns during a wet season. Later in the same month a medical gentleman asked my opinion upon a number of cases which had occurred in his practice in a particular circumscribed area. Some he said were undoubtedly follicular tonsillitis, others so closely resembled diphtheria that he did not know whether he ought not to notify. The onset was accompanied with headache and shivering. The throat was congested, the tonsils enlarged, and the crypts patent and sometimes plugged with muco-pus. The glands at one or both sides of the neck were enlarged. There was very little prostration, and recovery took place in from two to seven days. There was undoubted evidence of infectiousness.

In December, 1893, an outbreak of what was said to be diphtheria occurred in a parish at the border of my Chelmsford district. Two or three cases were notified as diphtheria and one child died of croup, but the medical attendant did not feel justified in notifying it as diphtheritic. From the resemblance of the cases to those previously described as due to influenza I regarded these as the same, and I had no reason afterwards to alter my opinion. There were two schools in the parish, but the outbreak was limited to the children attending one of these. Towards the end of last year my attention was again especially directed to a series of similar outbreaks. On Dec. 12th I found in one parish that forty-six children (twenty-nine families) had been or were away from school on account of "sore throat." In a typical case the child complained of feeling cold, sat over the fire, and shivered. The face was flushed and had an expression of weariness; the throat was a little sore, and there was a little headache, and sometimes pain in the limbs and generally weakness. The submaxillary glands were enlarged in a few cases, but not markedly so. The tonsils and pharynx were slightly congested. There was no infiltration. The patients usually got well again in from three to seven days. I found one or two cases fairly typical of influenza, and one case in which the pains in the limbs had been so severe that the parents called in a medical man, thinking that the lad was suffering from rheumatic fever. In another large village about the same time many children were absent from school on account of some undefined illness. The parish was an extensive one, and for some time past sporadic cases of scarlet fever and of diphtheria had been reported. The cases notified as scarlet fever were undoubtedly correctly diagnosed, but there is a doubt about the diphtheria cases. Cultures were made in three out of four notified cases, but no Löffler's bacilli were found, and in a piece of membrane from one throat which the Local Government Board asked Dr. Klein to examine for me he failed to find these bacilli. I examined a number of throats and obtained a very varied assortment of organisms, but nothing to indicate diphtheria. The children were ailing for a few days only, and a fair proportion had enlarged glands under the jaw. The swelling was so marked that many cases were regarded as mumps, but the patients I saw had no affection of the parotid gland. No cases of scarlet fever followed in any of the infected families and I do not think the affection was of that nature.

I will not quote instances in which sore throats were prevalent just prior to outbreaks of scarlet fever or diphtheria, but I may ask, Is the generally received opinion—viz., that these are mild cases of one or other disease—correct? Thrice recently I have investigated the nature of outbreaks of sore throat, associated in a minority of cases with a very slight and evanescent rash, which I very much doubted were scarlatinal in character, but which at a late stage of the epidemic merged in a few instances into well-marked cases of scarlet fever. The property of progressive infectiousness and increase in virulency is apparently common to both scarlet fever and diphtheria, but the slight cases of the former are not so industriously searched for as are those of the latter. During an epidemic of mumps, also, numerous slight and anomalous cases occur which it would be impossible to diagnose were it not known that parotitis was prevalent. The last series of cases of sore throat which I have examined was associated with an outbreak of mumps. In several infected families, whilst some members had all the typical symptoms, others had had headache, nausea, or actual vomiting, pains in the limbs, and sore throat, but no enlargement of the parotids. A medical man who attended some of these cases told the patients that they were suffering from "internal mumps." I wish in the next place to ask whether my recent experience with regard to diphtheria corresponds with that of other medical officers of health. The mortality during the past year has only been about 5 per cent. amongst the cases notified in the Chelmsford rural sanitary district, having in previous years been about 20 per cent. My last epidemic, not yet over, has included about thirty cases, all of which have terminated favourably. In the first family affected four out of five children were attacked, and one case for a time threatened to prove fatal. No diphtheria bacilli could be found in the membrane. As the cases occurred bacteriological examinations have been made, and only in one instance were any organisms resembling Löffler's found. In the case referred to, that of a lad aged eighteen, there was a well-marked membrane, but he was never confined to bed; in fact, he lived with the family (six children) as though nothing was the matter, smoked all day long, got better in about ten days, had no sequelæ, and none of the other inmates of the house have been affected or infected. I am inclined to think the bacilli, from their mode of growth, are the pseudo-variety described by Klein. I have already referred to the fact that in another parish four cases of diphtheria have been notified, and that in the three examined no diphtheria bacilli were found. Besides these several other isolated cases have occurred. A typical case is one which I recently examined at the request of a local practitioner. The patient was this practitioner's assistant. I was wired for, and found him in bed. Beyond a little malaise and sore throat he did not feel ill, nor had he had any symptoms such as usually occur premonitory to an attack of diphtheria. At first it was thought to be follicular tonsillitis, but the appearance of membrane on the uvula and tonsils indicated that it was something more than this. No bacilli were found in the culture made, but prior to observing this I had expressed my doubts as to the disease being diphtheria. The course of events in this and similar cases is as follows: One or more points in the mucous membrane of the tonsils, soft palate, or uvula become infiltrated, appearing paler than the surrounding mucous membrane. The patch becomes paler and paler until nearly white. It is but slightly, if at all, raised, and has no sharply defined margin. Before becoming white the infiltrating material may be absorbed and the part resume its normal appearance; but when it has assumed the milky-white colour it finally peels off, leaving a shallow ulcer which speedily heals. It may or may not be associated with a mild form of tonsillitis. The constitutional disturbance, as a rule, is very slight, but occasionally there are marked premonitory symptoms—headache, nausea, languor, and slight fever—but these speedily pass away and the patient feels fairly well.

If these are not cases of true diphtheria—and I am inclined to think they are not—it is time we adopted some other name for the disease, as at present our notification returns are rendered useless by their inclusion with diphtheria. It is probably a disease having distinct specific characters, and as it is undoubtedly infectious it is almost certainly due to some micro-organism. With reference to this portion of the subject I shall have more to say hereafter. How should the medical officer of health regard such cases? Strictly speaking, he has no business to diagnose them, but to accept all notifications sent in and act upon them in the usual manner. Many cases occur, however, in which no medical man is called in, and which the medical officer of health may, with the permission of the patient and relatives, examine and diagnose. Any error in diagnosis may be of serious import. If regarded as not being diphtheria, and subsequent events prove that it is true diphtheria, an epidemic may be the result. Where there is the slightest doubt, therefore, the only safe plan is to regard them as cases of diphtheria, and insist upon all precautions being taken to prevent the disease spreading. These precautions will very rarely include the compulsory closing of an elementary school, the brief duration of the disease and its apparently trivial character not rendering such a course necessary. Besides this epidemic form of pseudo-diphtheria there are probably several other throat affections which simulate true diphtheria. Nearly two years ago a brother medical officer of health sent me a large piece of transparent membrane from a child's throat, together with a note saying that it was the most marked case of diphtheria he had ever seen. The membrane appeared to consist entirely of spherical cells, apparently a form of torula, and upon streaking some agar jelly the growth consisted entirely of such cells, which, on account of pressure, when viewed under the microscope, appeared hexa-, octo-, or polyhedral. Soon after a sporadic case occurred in my district, in which the same organism occurred, associated with bacteria, and a few months later the same patient was again notified as suffering from diphtheria, and again the torula was the most prominent feature of the growth obtained from the throat. In the same parish a case of diphtheria was notified in January, 1895, which yielded a similar organism, and quite recently a fourth case has occurred. I sent a culture tube of this through the Local Government Board to Dr. Klein, and he states that he has on one previous occasion met with the organism in a case of membranous rhinitis. He is inclined to regard it as the thrush fungus. In the last two cases the torula was more usually oval in form, whereas in the former cases the organism was spherical. Possibly they are allied but not identical species. Whether they are the cause or merely concomitants of the disease it is at present impossible to say. This is a subject upon which I am at present working.

One thing is becoming clear, that under the name of diphtheria we are including two, if not several, distinct diseases, due to the development of different organisms on or in the mucous membrane of the throat. Amongst the countless multitude of micro-organisms which occur in nature it would indeed be wonderful if one only were capable of developing upon nature's medium and in nature's incubator and of injuriously affecting its host. During sleep the back of the mouth forms the incubator *par excellence*, and many different organisms flourish there, more than one of which are probably capable of penetrating the mucous membrane and causing its infiltration and exfoliation, and the products of their metabolism, toxines, &c., becoming absorbed may be the cause of constitutional disturbances such as those described in connexion with the epidemics of "sore throat."

Chelmsford.

TWO CASES OF HYDATID DISEASE SURGICALLY TREATED.

BY W. J. COLLINS, M.D. LOND., F.R.C.S. ENG.,
SURGEON TO THE LONDON TEMPERANCE HOSPITAL; ASSISTANT SURGEON TO THE ROYAL EYE HOSPITAL, SOUTHWARK.

THE two following cases of hydatid disease which have come under my care during the last twelve months are, perhaps, worthy of record: the one on account of the rarity of the situation of the cyst—in the axilla—and the interesting diagnostic problems to which this accordingly gave rise; the other as further illustrating the success attending surgical treatment of even large and adhesionless hepatic hydatids.

CASE 1.—A young woman aged nineteen years, with a good family history and no previous ailments, first noticed a painless lump in the right axilla in August, 1893. She kept a pet dog, and also lived in a notoriously overcrowded and insanitary area. The diagnosis remained uncertain until the operation, although fatty tumour and chronic abscess had been suggested. The swelling was two inches and a half in diameter, and freely movable under healthy skin. She was admitted to the London Temperance Hospital on May 10th, and on the 21st she was placed under chloroform and an incision was made into the swelling. Clear fluid escaped and a white hydatid cyst shelled out; there was a fibrous quasi-sheath around this, composed of thickened tissues. Hooklets were found in a scraping of the cyst-wall. Healing progressed uninterruptedly, and the patient was discharged well on June 1st.

CASE 2.—A single woman aged thirty-three years noticed a swelling at the pit of the stomach in September, 1893. This was at first painless, but, increasing in size, began to be tender, and in December, 1894, she was admitted into the medical wards of the London Temperance Hospital under the care of Dr. Fletcher Little. I saw the case in consultation and diagnosed hydatid of the left lobe of the liver, and an exploring syringe verified the diagnosis by yielding hooklets in the withdrawn fluid seen under the microscope. She was accordingly transferred to my ward with a view to operation, the nature of the case and the treatment suggested having been explained to the patient, and her assent obtained. The patient's previous and family histories were good, and she appeared to be in fair health, with the exception of the abdominal tumour. Occupying the epigastrium and encroaching on the left hypochondrium was a firm, globose, slightly elastic swelling which gave a feeling of fluid, especially when bimanually palpated with one hand deeply pressed into the left ilio-costal space. The swelling was a little tender, dull on percussion, without any specific fremitus, and dumb. Its area of dulness was continuous with that of the liver. The heart was displaced a little upwards. On April 8th, 1895, Dr. L. Wilde administered chloroform, and I opened the abdomen by a median epigastric incision. The left lobe of the liver was unusually prominent and presentable and gave to the examining fingers the feeling of a bag tense with fluid. I inserted an aspirating trochar and withdrew thirty-seven ounces of opalescent fluid. Closing the enlarged opening with my finger, and later with swabs, while flat sponges were packed around the wound, I sutured the thinned and now flaccid liver lobe to the anterior abdominal wall, with little, if any, escape of hydatid fluid. The large cyst cavity was then completely emptied by suction with a glass syringe and a piece of india-rubber tubing attached to its nozzle. A large empyema drainage-tube with a flange was then inserted, and india-rubber sheeting fitted round it, over the gauze dressing, and brought out through a many-tailed bandage. The next day the patient was free from pain, the temperature was normal, and many ounces of fluid had come through the tube. Progress to recovery was uninterrupted; the highest temperature recorded was 99·4° F., on the eighth day. The fluid discharge gradually became less, portions of cyst-wall came away in abundance, and when collected there was sufficient to fill a four-ounce vessel. The fluid became more puriform; the tube, which was progressively shortened, was left out on June 13th, and the patient was discharged on July 18th, being quite well.

Albert-terrace, N.W.

A CASE OF CHRONIC GLANDERS IN A HORSE-SHOER.

BY GORDON SHARP, M.B., C.M. EDIN.

IN May, 1892, I saw a man aged twenty-three, engaged as a shoeing smith, who had worked among horses for years; the following was the history of his complaint. Three months previously to the time when I saw him he began to suffer from a disagreeable, foul-smelling, watery discharge from the left nostril. He consulted a medical man, who told him he had polypi of the nose. He gave him medicine to take and snuff to apply to the nostril. A week or two passed, and as the man did not improve

Digitized by Google

he went to the infirmary of the town in which he then lived and was admitted. There he remained for a few weeks and had some slight operation performed on the nostril, but without benefit, and he left the hospital and placed himself under the care of a consulting physician; but not only did the nostril not get well, but the eye on the same side became affected in the same manner as the nostril. After some weeks he sought relief at one of the Manchester hospitals and remained under treatment for a short time, during which some operative treatment was performed in the shape of scraping the nostril, followed by the application of caustics. The patient's condition got worse and he came home to his father's house, where I first saw him. From what has been said it will be seen that the disease had already ran fully a three months' course from the time of its being first noticed by the man himself. On

FIG. 1.

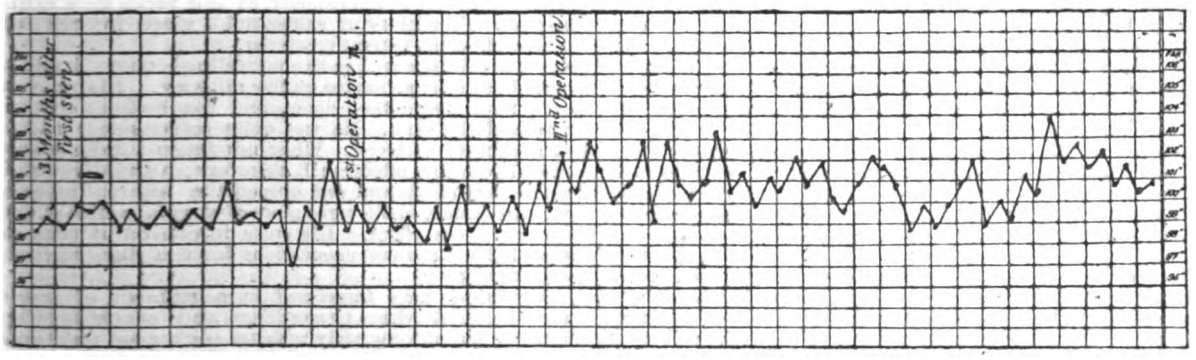

Chart showing course of temperature.

examination the patient was found to have a foul watery discharge occasionally during the day, tinged with blood and pus, discharging from the left nostril. The nostril itself was red, and in parts it showed black sloughs, which on being removed revealed an underlying ulcerated surface. The left eye was red and inflamed and discharging fluids of the same character as the nostril. Immediately below the eye the tissue of the face had sloughed away, and the bone beneath was covered with black sloughs. The treatment at this stage consisted in removing the sloughs and making the parts as sweet as possible by the frequent application of strong corrosive sublimate lotion, followed by iodoform. The diet was generous, and a simple tonic

FIG. 2.

Illustration showing ragged state of the parts. Upper jaw-bone.

mixture was prescribed. There was no reason to suspect syphilis. For about three months the condition appeared as if improving, but at the end of this time the temperature gradually rose, getting as high as 100° or 101° F. in the evening; and at the same time the tissues of the nose and cheek rapidly necrosed, and in a fortnight's time a considerable area of the upper jaw-bone was laid bare and the side of the nose had nearly gone. Inside the mouth the hard palate was covered by a black slough, and an opening at the side of the nose on the left side led into the mouth. It was now felt that some drastic operative treatment was imperative, and it was only now that consent was obtained. It was by this time fully seven months since the disease was first noticed by the patient himself. The amount of tissue of the nose and cheek which had sloughed was so great that it was absolutely necessary to remove the upper jaw-bone, and with it the adjacent small bones, such as the nasal and lacrymal, in order to close up the wound, allowing for tissue necessary to be removed on account of its being unhealthy. On removing the bones a granulating mass the size of a walnut was discovered on the inside of the cheek, and exuding a foul discharge of the character already mentioned in connexion with the nostril. The force necessary for the removal of the bony mass caused the thin, carious anterior wall of the maxillary antrum to give way, and there exuded a dark-yellow thick pus intensely foul in odour. All the diseased tissues were removed, and strong nitric acid was applied to the granulating mass. The various parts were washed with strong corrosive sublimate lotion and then dusted over with iodoform, and a presentable face was the result. The bones removed were found soft in parts, especially over the anterior wall of the antrum. Black sloughs covered other parts, while in still other parts the periosteum showed red points. The pathological condition was evidently that of an infective cario-necrosis, but not of an acute type; but when an examination of the decalcified bone is made, the exact condition will be made out. The microscopic character of the discharge will be considered when I speak of the differential diagnosis. Although the eye was red and painful there were no special indications for its removal, and it was spared at this time. Improvement was marked for a week, but by the eighth day the edges of the wounds looked red and soon gave way, and rapid sloughing took place. The eye, too, became inflamed, and in less than a fortnight after the first operation the left eye had to be removed for a general inflammation of the organ. Between the seventh and the tenth days after the first operation the temperature showed a gradual rise, with unpleasant constitutional symptoms. The removal of the eye and scraping away of the necrosed tissue were attended by no benefit either local or constitutional. The lymphatic glands in the neck and under the jaw were not much enlarged, and although there was occasionally some bronchial catarrh the lungs were not markedly affected. The temperature kept high, especially at night, but it varied. Some nights it reached 101°, 102°, or even 103°, with a morning fall of one, two, three, and once of nearly four degrees. On the whole the tendency was for the temperature to keep high, but on one or two mornings there was a fall to nearly normal. One evening it went up to 105°. The course of the temperature pointed directly to a septicæmic process. Side by side with the rise in temperature the disease increased locally. The septum of the nose entirely necrosed, the remainder of the nose sloughed away, the bones of the other side were attacked, and the patient presented a horrible appearance, and despite the assiduous application of antiseptics the odour was overpowering and the necrotic process rapid in its increase. The discharge remained of the same kind throughout the entire course of the disease

Digitized by Google

The man lingered on for a longer period than one would have expected from the large amount of local mischief, and the constitutional effects were less potent than one would have imagined, more especially that for months the patient must have carried some of the discharge into his stomach with every meal partaken of. He finally died of exhaustion some fifteen months after the first onset of the disease. An examination of the body after death was not obtained.

The diagnosis is difficult, but can be arrived at partly—(1) by exclusion; (2) by remembering the man's employment; (3) by the character of the discharge and its microscopic examination; and (4) by the seat of the disease. Syphilis is excluded by the history, by the absence of other signs, and by the little effect that mercury had on the course of the disease. Actinomycosis was thought of, but an examination of the pus from the antral abscess showed no ray fungus. A simple infective necrosis was excluded by the chronicity and by the elective seat of the disease. Cancrum oris was thus excluded. One is narrowed down to accept chronic glanders as the true diagnosis, and in favour of this we have (1) the man's employment as a shoeing-smith; (2) the original position of attack of the disease—namely, the nose; (3) the nature of the discharge, offensive, watery, and often tinged with blood and pus; (4) the extensive necrosis of soft parts, bones, and cartilage; (5) the fatal results; and (6) the microscopic revelations. A specimen of the discharge was placed on a cover-glass, dried in the flame of a spirit lamp, and stained with alkaline methylene-blue, washed in very dilute acetic acid, then in water for a considerable time, and dried and mounted and examined under both low and high powers. No characteristic club-shaped bodies could be seen as found in actinomycosis, but organisms something of the size of the tubercle bacillus were seen in great numbers. Whether these were the bacilli mallei of glanders I am unable to say for certain, for I was at the time unable to find a detailed description of that organism; but altogether the chances are that they were so. (Since writing the foregoing I have been able to satisfy myself that they were the bacilli in question.) Glanders is a very rare disease in the human being, and especially so in Great Britain, and if we take 100,000 deaths probably hardly one is due to this affection. Thus every case which occurs is of sufficient interest to be worth publishing.

Leeds.

TRANSFUSION OF SALINE FLUID; SIX SUCCESSFUL CASES.

BY NATHAN RAW, M.D. DURH., &C.,
MEDICAL SUPERINTENDENT AND PATHOLOGIST, DUNDEE ROYAL INFIRMARY.

HAVING for some years employed transfusion of saline fluid in all cases of hæmorrhage where a fatal issue threatened, I beg to place on record some successful results in the hope of encouraging others to adopt this simple and efficacious means of saving life in these cases.

CASE 1.—A young woman aged twenty-four years, suffering from all the symptoms of gastric ulcer, went for a walk and was seized with violent hæmatemesis. She fell fainting in the street and was carried to hospital. It was estimated she had lost several pints of pure blood. On admission to the Bolton Infirmary she was quite unconscious and pulseless, conjunctival reflex was abolished, the respiration was sighing, and the extremities were cold and clammy. She was given the ordinary styptics, ergotinin, &c., but as she was rapidly sinking she was transfused with normal saline solution—one drachm of chloride of sodium to a pint of sterilised water heated to 100° F. Altogether four pints were injected into the median basilic vein, with wonderful effect. She slowly recovered and is now (four years later) quite well.

CASE 2.—The patient, a woman, was suffering from exhaustion through long-continued suppuration of the knee-joint, which was amputated. The immediate shock of the operation was sufficient to cause serious syncope, although very little blood was lost. Immediately after amputation of the thigh she showed serious symptoms of collapse and was pulseless. The median basilic vein was at once opened, four pints of the fluid were injected, and at the same time internal stimulants were given and external heat applied. In a short time she revived and made a good recovery.

CASE 3.—A robust man was admitted to the infirmary with compound depressed fracture of the occipital bone, opening into the lateral sinus. He was brought in as dead, having lost an enormous quantity of blood. I at once elevated the bone, removed a large piece (2 in. by 2½ in.), and plugged the lateral sinus with gauze. I then transfused him with four pints and a half of saline solution, with the result that he made an excellent recovery and is now at work.

CASE 4.—A man was admitted who had cut his throat. He was found by the police in a field, where he had lain all night. On admission he was unconscious and pulseless. He was at once transfused with the fluid (3½ pints) and slowly recovered.

CASE 5.—A young man aged twenty years was admitted "carried on a door." He had a large varicose ulcer which had suddenly opened into the internal saphenous vein. On admission he was unconscious and pulseless, with sighing respiration. The median basilic vein was opened, but it was difficult to introduce the cannula, as the veins were so much collapsed. Four pints of saline fluid were injected, with the result that the patient recovered.

CASE 6.—This proved to be a marvellous one. A man was knocked down by an engine on the railway. His right arm was cut off above the elbow, and he had a compound fracture of the skull. He was quite unconscious and had lost a quantity of blood. When admitted I did not expect him to live many minutes; I, therefore, hurriedly tied the main vessels of his arm and opened the internal saphenous vein. I injected, in all, eight pints of normal saline solution, with marvellous effect. His pulse improved at once, and although he remained unconscious for ten days he made a good recovery.

Remarks.—I have transfused in a number of cases of severe accident where hæmorrhage and shock have been combined, but unfortunately without such good results as in hæmorrhage only. The *modus operandi* is simple. An incision two inches long is made obliquely in the line of the vein, which is tied with a single loop of catgut at its lower end, a loose ligature being placed at the upper end of the vein. Between the ligatures the vein is opened, and a small straight glass cannula is introduced. To this are attached two yards of small rubber tubing with a small glass funnel holding four ounces. The cannula is securely tied in the vein, and then all is ready. The greatest care must previously have been taken to exclude all air from the tubing and cannula by filling them with the solution. The solution is prepared by adding one drachm of chloride of sodium to each pint of carefully sterilised water heated to 100° F. The fluid is poured in slowly and the limb raised to allow it to flow more easily. In this way several pints may readily be introduced. After sufficient has been given the vein is tied above and below, the skin sutured, and the wound dressed antiseptically. I have often left the cannula in the vein so as to allow more fluid to be injected on different occasions at short intervals. In my opinion the only danger to the patient is from the introduction of air; but with care this can always be avoided. The procedure is so simple that I can strongly recommend its use, as sometimes apparently most hopeless cases may be saved.

Dundee.

A VACCINATOR'S DEPUTY.—Some weeks ago, it will be remembered, the Local Government Board inspector, in complaints which he made against two public vaccinators of the East Preston (Sussex) Union, protested against the regular employment by such officers of deputies. Both gentlemen were communicated with and their subsequent explanations referred to the Board. One, who undertook to amend matters, is no further referred to. In the other case, however—that of Mr. Evershed of Arundel—the Local Government Board think that if he is unable or unwilling to perform habitually in person the duties which he had undertaken the guardians should terminate their contract with him and appoint some other medical practitioner as public vaccinator. It is stated that in 1892 Dr. Sweeting cautioned Mr. Evershed upon this point and another with respect to the keeping of his register. This decision having been communicated to Mr. Evershed, he has now tendered his resignation of the office. It may be worth adding that another Sussex medical officer has since resigned in one of the western unions, and gives as his reason that he can no longer himself undertake the duties of the office.

LONDON HOSPITAL.

A CASE OF CHRONIC INVERSION OF THE UTERUS CURED BY AVELING'S REPOSITOR; REMARKS.

(Under the care of Dr. G. E. HERMAN.)

WE have lately published in the columns of THE LANCET[1] the account of a case of inversion of the uterus of recent origin, where treatment by manipulation was successfully carried out and the reduction effected in a short time under an anæsthetic. In the following case the inversion was of six months' duration and required a more prolonged treatment to effect a cure; it was, in fact, one of those for which this repositor was specially made. The mode of action of this instrument is thus described in the communication made by Dr. Aveling, as referred to by Dr. Herman. Reduction takes place by the cervical method. Newnham advised this method of reinversion in 1818. He said: "It is wisest and best to endeavour to reinvert the uterus by returning first that portion of it which was last expelled from the os uteri." Pressing on the uterus causes counter-vaginal traction on the cervix, making it unroll gradually until the internal os is reached, where a little delay is caused by its being less dilatable. When this point is passed the body of the uterus soon opens and admits the cup. The last step must take place rather suddenly, for all patients say that something has "given way" and comparative comfort is the result. For the notes of the case we are indebted to Mr. W. Eardley, clinical clerk.

A patient aged twenty-three was admitted into the Victor Ward of the London Hospital on Nov. 21st, 1894. She had had one child, born in the preceding May. The labour was difficult; instruments were used, there was much bleeding afterwards, and she kept her bed for six weeks. She had never been well since, having been losing blood almost continuously. When not losing blood she had a yellow discharge. She had had no pain. On vaginal examination a rounded swelling about the size of a walnut was felt projecting through the os uteri. The patient did not manifest pain when it was touched. The sound could not be passed up beside it, and by bimanual examination it was found that the body of the uterus was not situated in its proper place above the cervix. The diagnosis of inversion of the uterus was clear. On Nov. 30th Aveling's repositor was applied, the tapes being so fastened that the elastic bands by which the upward pressure was applied were moderately tense, but not at the utmost tension they would bear. The repositor caused a good deal of pain, with at first vomiting. It was removed, the state of the uterus examined, and the repositor readjusted on Dec. 1st, 3rd, 5th, 8th, 11th, 13th, 15th, 17th, 19th, and 21st respectively, various changes being made in the size and shape of the cup used, but the tension on the elastic bands being about the same. Each time the repositor was removed it was found that the inversion was unreduced, although it was thought that the fundus uteri was pushed a little higher up. The patient had suffered a good deal from pain and nausea while wearing the repositor, and therefore she was allowed a few days' rest before proceeding further. On Jan. 18th of this year the repositor was again adjusted; but this time the tapes were so secured that the elastic bands were stretched to their utmost tension. On the 20th the uterus was still unreduced. On the 21st the patient's temperature was 102° F. and she complained of great pain. On examination the cup was found within the cervix, the fundus uteri being in its normal position. The patient was discharged cured on Jan. 29th.

Remarks by Dr. HERMAN.—Inversion of the uterus is so uncommon, and so short a time has passed since it was regarded as incurable and often treated by amputation, that cases which exemplify its curability are still worth reporting. The case above related shows an important practical point, which is that for the reduction of chronic inversion of the uterus pressure must not only be continuous but powerful. Reposition did not take place until the elastic bands had been so tightened that their utmost power was exerted. More gentle pressure, though continuous, and protracted with short intervals for three weeks, failed to cure. I regret that I did not measure the tensile strength of the bands. Dr. Aveling, in his latest account of his repositor and its use,[2] laid stress on the importance of seeing that the instrument was furnished with elastic bands of the proper kind, from which I gather that he had found that power as well as continuity of pressure was needed. The case shows also another and less important point—viz., that great tenderness of the inverted uterus is not always marked enough to be of use in distinguishing the inverted uterus from a polypus.

[1] THE LANCET, July 27th, 1895.

VICTORIA HOSPITAL, BHOPAWAR AGENCY, CENTRAL INDIA.

CASE OF NEURALGIA OF KIDNEY; NEPHROTOMY; RECOVERY.

(Under the care of Surgeon-Lieutenant-Colonel DUKE.)

NEURALGIA of the kidney, independently of the presence of calculus or gross change, is a condition which is not usually mentioned in our text-books or even in special treatises on the subject of renal disease. It has, however, been long recognised that in certain cases of painful kidney, when stone was suspected from the symptoms and nephrotomy performed, relief might follow, although no stone was found. More than this; in two cases with this history no disease was found after thorough examination of the affected kidney on a subsequent occasion. The proof afforded by these two cases is of great importance, for the difficulty experienced in feeling a stone through the kidney substance is frequently insuperable, and at the first examination of these cases the renal pelvis does not appear to have been explored. Dr. L. McLane Tiffany[1] of Baltimore cut down on a kidney the seat of intense and recurring neuralgia of several years' duration, explored it thoroughly, and, not finding any stone, split the capsule for three inches and obtained a cure. The incision was made through the capsule with the idea of relieving tension.

The patient, a fine-looking widow aged thirty-five, childless, had suffered for more than four years from attacks of agonising pain in the left loin. She could fix the spot with her thumb, this being a point a little below, and close to, the left twelfth rib. A circular scar, the result of "firing" in previous years, was visible here. In character the pain was paroxysmal, while the agony endured was most acute, the body being doubled up in severe colic, and the teeth and hands clenched. The attacks lasted from half an hour to two hours, being often followed by a good deal of exhaustion. They came on two or three times a month, and from being a strong, powerful woman she became thin and weak. In the intervals her health was good. Morphia injections, Indian hemp, chloral, and bromides gave merely temporary relief; but during the acme of an attack only chloroform anæsthesia was of any practical use. Menstruation was scanty. Vaginal examination showed neither tenderness of the ovary nor disease of the womb. The urine was normal. No gravel or blood had ever been passed. Thus stone in the kidney and ureters, as well as ovarian and uterine mischief, were excluded. Movable kidney alone remained to diagnose. The most careful examination under chloroform, however, failed to detect any movement or transposition of this organ. The diagnosis could not be determined, but the woman prayed for relief. About this time, in the *Medical Annual* for 1894, under the heading "Surgery of Kidney," I read evidence which convinced me that the patient was suffering from neuralgia of the kidney, and that nephrotomy might cure her. That journal quotes a case under the care of M. Guyon in which nephrotomy was performed, the patient having all the classical symptoms of renal calculus. No calculus was found, but the patient was relieved. Similar cases are

reported by Sobater, Durham, Reynaud, Tiffany, Bloch, and Hurry Fenwick. The diagnosis having been now settled, and as the patient, whose life was a burden to her, implored for relief, it was determined to operate. On July 1st, 1894, assisted by Surgeon-Major Mosse, A.M.S., the operation was carried out. Owing to the presence of fat, the last rib was made out with difficulty. An incision five inches in length was then made parallel to and three-quarters of an inch below the last rib, dividing the usual structures and exposing a layer of fat of considerable thickness. This was cut through, as well as were the deeper fascia and fibres of the external oblique, leaving a wound of considerable depth, so that the structures were not so easily defined *in statu* as they are graphically described in print. More muscular fibres, including the edge of the quadratus lumborum, required division, the latter freely with scissors. By dilating the parts the kidney was just drawn into sight, and the fat and fascia covering it were opened, when the gland, looking very livid and congested, came into view. By firm pad pressure from the front, aided by Thornton's broad forceps fixed to the fascia, the kidney was raised and drawn well into the wound. Its convex surface, along the whole length, was then incised to the depth of one-tenth to one-eighth of an inch. A crucial cut was next made to the same depth. The bleeding which followed was easily checked by sponge pressure. The wound was now freely irrigated by carbolic solution (1 in 40), which appeared to act strongly on the tissues. (This is noted, as Surgeon-Lieutenant-Colonel Duke thinks that absorption took place with subsequent irritation.) A drainage-tube having been laid along the whole length of the kidney, the deeper wound was closed by three and the upper by six (No. 13) Chinese silk sutures. Ferrocyanide gauze and cotton wool, held in position by a wide flannel bandage, completed the dressing. The operation occupied upwards of an hour. Half a grain of morphia was subsequently injected subcutaneously. The after-progress was as follows. On July 1st, at 10 P.M., there was much sickness, burning pain in the wound (tension), and also some abdominal pain. On the 2nd, at 7 A.M., the dressings were changed, as they were soaked with serum. At 10 A.M. vomiting, nausea, and abdominal pain occurred. There was still severe burning in the wound. At 5 P.M., fearing peritonitis, and acting on Mr. Lawson Tait's advice, the following draught was given: three drachms of sulphate of magnesia, one drachm of sulphate of soda, and two scruples of potassio-tartrate of soda, in two ounces of very hot water. At 10 P.M. there had been no vomiting since the administration of the saline draught. The pulse was 120 and the temperature 102° F. Fifteen grains of antipyrine, given to reduce fever, were vomited with green bile. A second dose of fifteen grains was retained. On the 3rd the bowels were moved freely once in the night. At 10 A.M. the dressings were changed. The wound was found to be quite sweet. There was very little red sanious discharge; owing to their evident tension, Surgeon-Lieutenant-Colonel Duke removed the highest and the lowest sutures. The urine was smoky, like that of carbolic acid poisoning. An effervescing draught was given with prussic acid and belladonna, and repeated at 4 P.M. At 9 P.M. the urine was coffee-coloured. The patient was in much distress. The bowels were moved four times in the day. At 10 P.M. the pulse was 116 and the temperature 102°. One-sixth of a grain of pilocarpine with ten minims of water were subcutaneously injected as a diuretic. At 10.30 P.M. fifteen grains of antipyrine were given in an effervescing draught. On the 4th, at 10 A.M., the patient was cheerful and had passed a good night. The pulse was 100. The urine was almost normal in colour. The wound was sweet, with very little discharge. Three more sutures were removed (unwisely). At 4 P.M. there were signs of menstruation. On the 5th, at 10 A.M., the wound was still sweet, and the remaining suture was taken out. The wound had united in the centre, but not at the upper and lower edges. Strapping was applied. The patient was very cheerful. The abdomen was lax and free from all pain. On the 7th the patient was doing well. On this day Surgeon-Lieutenant-Colonel Duke went on leave, and Surgeon-Captain Davoren, A.M.S., kindly took over the case. To curtail the report, it is only necessary to add that the sutures were removed too soon. In consequence the edges gaped, and the wound did not heal by granulation until July 27th, when only a small drainage-tube opening remained, all eventually closing well and strongly.

Remarks by Surgeon-Lieutenant-Colonel DUKE.—Speaking generally, the chief difficulty in either medicine or surgery is correct diagnosis; this once definitely settled, a certain line of treatment can usually be satisfactorily carried out. The case described above is one where a correct diagnosis was attended with difficulty. The patient was examined by me eleven months afterwards. The parts were firmly healed, and there was no tendency to bulging or weakness of the wall. Since the day of the operation there has been no return whatever of the original pain; and, as far as this is concerned, the patient is cured.

Reviews and Notices of Books.

Leprosy in its Clinical and Pathological Aspects. By Dr. G. ARMAUER HANSEN, Inspector-General of Leprosy in Norway, and Dr. CARL LOOFT, formerly Assistant Physician to the Lungegaards Hospital. Translated by NORMAN WALKER, M.D., F.R.C.P. Edin., Assistant Physician for Dermatology, Edinburgh Royal Infirmary. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent and Co., Limited. 1895.

THIS work, illustrated as it is with numerous photographs and coloured plates of the microscopical appearances of the disease, strikes us as an excellent contribution to the subject of which it treats. In less than 150 pages, if we exclude the plates, the authors have succeeded in telling us all that is really known about leprosy in its clinical and pathological aspects. They speak from a large and extended experience and have taken every advantage of their opportunities to verify their observations and present the reader with a comprehensive statement of the result of their studies. The book is written in a scientific spirit and lucid style, and appears to have been very well translated by Dr. Norman Walker. The chief feature of the book is the manner in which the course of the disease is explained by the development of the special bacillus to which the disease is now—and correctly in our opinion—attributed, for the bacillus lepræ can be demonstrated in all leprous products, and we may practically conclude that leprosy is a chronic disease caused by it. Since the publication of Danielssen and Boeck's work in 1847 leprosy has been clinically recognised in two forms, the "nodular" and "anæsthetic"; but, as the authors observe, this nomenclature cannot be regarded as, scientifically speaking, accurate, for the line of demarcation between them is not always easily defined. Skin affections are present in both forms, and the nerves are affected in the nodular as well as in the other form, although not in the same striking way. Still the division corresponds to two clinical types under which a majority of the cases of leprosy can be arranged, and has, moreover, been generally accepted. The authors, recognising the importance of not unnecessarily disturbing an existing and familiar nomenclature, describe the two forms of the disease as *Lepra tuberosa* and *Lepra maculo-anæsthetica*. As the leprosy bacillus is present in both forms, and in every case of nodular leprosy sooner or later the nerves become involved, if only the patient lives long enough, it may be taken that there is an essential unity between the two forms, and the authors consequently do not recognise the name of "mixed leprosy." Chapter II. is taken up with a graphic and interesting description of nodular leprosy, easily diagnosed as a rule by its characteristic skin affection. Chapter III. describes the structure and the microscopic and bacteriological appearances of the leproma, with the aid of some admirable illustrative plates. Chapters IV. and V. treat of lepra maculo-anæsthetica and its pathological anatomy. These chapters are excellent. The diagnosis and prognosis of the disease, its etiology and treatment, with numerous tabular statements, follow. Isolated extracts taken here and there from the volume would

only give [the reader a meagre idea] of its merits: the book requires to be read as a whole, and we advise all who are interested in the subject to do so for themselves, for it contains much valuable information about this terrible disease. The authors regard the isolation of lepers as the only reliable means by which the spread of the disease can be checked, and they furnish some important statistical evidence of what can be accomplished in this respect. The disease is dependent on a bacillus, but the inquiry hardly narrows itself down into a study of the means by which the bacillus effects its entrance into the body, though study in this direction affords room for interesting inquiry. It does not seem that the exhibition of any known bactericide cures the disease, although patients occasionally recover.

Lectures on Genito-urinary Diseases. By J. OGILVIE WILL, M.D., C.M., F.R.S.E., Consulting Surgeon to the Aberdeen Royal Infirmary and Examiner in Surgery in the University of Aberdeen. London: The Scientific Press, Limited. 1894.

THESE six lectures have the great merit of being thoroughly practical and of giving the results of mature experience in dealing with a frequently occurring class of ailments. Urethral fever, catheter fever, and the treatment of retention of urine are subjects of abiding interest to every surgeon, and it is to the consideration of them that Dr. Ogilvie Will devotes his opening chapters. He ascribes to Sir Andrew Clark the credit of drawing the attention of the profession to certain dangers of ordinary catheterism, the least serious of which is a well-marked but short attack of pyrexia following the dilatation of a stricture by means of a bougie. This attack is usually ushered in by a rigor, which supervenes most commonly in the next act of urination. The temperature may rise to 104° or 106° F.; there is profuse sweating, and next day the patient is quite well, or nearly so. This is the so-called urethral fever, and is insignificant in comparison with the symptoms which catheterism may set up in men suffering from retention due to enlarged prostate. In these cases the patient two or three days after the commencement of catheterism becomes sick and feverish, and may gradually lose strength until his sufferings terminate in death after the lapse of three or four weeks. Post mortem the bladder is found to be inflamed and sloughy, the kidneys are riddled with small abscesses, and micrococci abound everywhere. The most probable explanation of these pathological changes is, in the author's view, the introduction of putrefactive atmospheric germs into the bladder along with air admitted through the empty catheter, and the obvious preventive is never to completely empty an over-distended bladder. For retention caused by strictures too tight to admit a No. 1 English catheter the author recommends the passing of a filiform bougie, followed by a metallic catheter screwed to its end. For prostatic retention he generally employs Mercier's elbowed catheter. Silver catheters should never be fastened into the bladder, but flexible instruments may be left in position. The remaining lectures are on Gleet, Hydrocele, Varicocele, and the Treatment of Acquired Syphilis. The author regards syphilis as curable, and is in the habit of giving mercury continuously for the first six months, commencing its use during the primary stage. The work bears a somewhat too comprehensive title; it can, however, be highly recommended as a text-book on the subjects of which it treats.

Atlas of the Diseases of the Skin. By H. RADCLIFFE CROCKER, M.D., F.R.C.P., Physician to the Department of Diseases of the Skin, University College Hospital. Parts VII. to X. London and Edinburgh: Young J. Pentland.

THE four parts of this most admirable atlas which have appeared at regular bi-monthly intervals since our last notice fully maintain the high standard of excellence with which the publication commenced. With hardly an exception the drawings are strikingly natural and have been reproduced with much fidelity, whilst the accompanying text is for the most part wisely limited to a brief description of the disease depicted and the history of the case from which the drawing was made. Each part contains six plates, and as some of these bear more than one figure, it is clear that when finished the Atlas will be as complete in range as it is excellent in design. Amongst the drawings to be found in the parts before us which may be singled out for special mention are those of prurigo, impetigo contagiosa, psoriasis guttata, and pigment anomalies in Part VII.; of herpes and of psoriasis in Part VIII.; of hydroa herpetiformis, psoriasis punctata, and ichthyosis congenita in Part IX.; and of elephantiasis, seborrhœa, alopecia areata, and tinea versicolor in Part X.; but where the general standard of excellence is so good it is not easy to make any marked selection. In Part VII. there is an illustration of the severe disease, pemphigus vegetans, the text giving a detailed description of the clinical features of the case and the post-mortem examination. The illustration of Barbadoes Leg (elephantiasis tropica) in the same part is from a museum specimen of the amputated leg of a negro in Barbadoes. The characteristics of chloasma uterinum, leucoderma, and melanoderma are well shown in the drawings to be found in this part; and we may contrast with these pigmentary disorders the remarkable cases of argyria and chrysarobin erythema which are depicted in Part VIII. That of argyria is singular in the fact that the only apparent source of the silver impregnation was the use of a gargle of nitrate of silver thirty years previously. An illustration of xanthema diabeticorum serves to evoke an account of the points of distinction between this and the ordinary form of xanthema. The subjects of rodent ulcer and epithelioma are illustrated by eight figures, including one of "Paget's disease" of the scrotum. One of the plates in Part X. contains four figures of some of the more frequent "vaccination eruptions"—viz., impetigo, vaccinia-lichen, and a peculiar rash of erythematous type spreading from the vaccinal site and attributed to microbic infection. We can only reiterate our belief in the great value and utility of this work, for the production of which both author and publisher deserve much commendation.

An Australian in China. By G. E. MORRISON, M.B., C.M. Edin. London: Horace Cox. 1895.

ANY book about China will be read at the present moment with increased interest, on account of the terrible massacres of our fellow countrymen that have recently taken place. Dr. Morrison, who travelled from Shanghai along the Yang-tse-Kiang as far as Sinfu, and then turned off in a south-westerly direction to make his way to Burmah, has written a most readable and interesting book. He gives us a more favourable impression of the country than we are accustomed to hear from modern travellers, and, indeed, he seems to have met with nothing but kindness and courtesy; but, then, his mission did not clash with existing interests. His plan was not to make himself offensively ostentatious, but to let the Chinese really understand that he was their superior, and occasionally to be condescending. We are convinced from our experience of travel in the East that this is the best way of dealing with Orientals. Rudeness must be carefully avoided, but on the other hand the "distinguished stranger" attitude must be carefully preserved. Dr. Morrison shortly sums up the Opium Question thus: "The Chinese do not want our opium—it competes with their own." This, we fancy, is the whole question in a nutshell. Chinese medicine is much more complicated than that of the West,

Digitized by Google

and the great thing to be able to do is to feel the pulse correctly. "The pulses of a Chinaman vary in a manner that no English doctor can conceive of." We commend the following to the notice of Dr. Oliver for his next edition of "Pulse Gauging": "Death is no further off if the pulse seems like a fish whose head is stopped in such a manner that he cannot move, but has a frisking tail without any regularity; the cause of this distemper lies in the kidneys." We might go on quoting the whole of Dr. Morrison's delightful book, but we will instead recommend everyone to read it. Anyone will be interested with it, and anyone who has ever "heard the East a-callin'" will be doubly charmed.

Analytical Records FROM THE LANCET LABORATORY.

DRY IMPERIAL CHAMPAGNE "SANS SUCRE."

(MOET AND CHANDON; LONDON: SIMON KINGSCOTE AND CO., CRAVEN HOUSE, NORTHUMBERLAND-AVENUE, W.C.)

IT is well known that champagne is "forbidden fruit" to many on the score of its burden of sugar—a fact which has led Messrs. Moet and Chandon to introduce a wine possessing all the esteemed characters of a choice vintage champagne, yet which may be taken as freely and as safely as claret as regards its sugary constituents. In view of the importance of this introduction in connexion with its reputed adaptation to the requirements of those to whom sugar is prohibitive or objectionable, we submitted the wine to exhaustive analysis with results which were very satisfactory in this regard. It contained alcohol, by weight 11·38 per cent., by volume 14·09 per cent.; extractives, 2·43 per cent.; total sugar, 0·65 per cent.; total acidity reckoned as tartaric acid, 0·98 per cent. One pint of the wine contains, therefore, about 60 grains of sugar, an amount which is one-tenth less than that of some wines, and at least one-third less than that contained in the generality of specimens. The presence of a small quantity of extractives is furthermore in its favour for the special requirements indicated. In short, it is a generous, exhilarating wine by no means lacking the agreeable qualities of an excellent brand of champagne, yet containing but a minimum of those constituents which may be prejudicial.

KARSWOOD CREASOTE.

(E. G. HUGHES, VICTORIA-STREET, MANCHESTER.)

Karswood creasote is described as a new distillate of "sweetwood" creasote, and is, we find, a very pleasant-smelling, aromatic, clear, colourless, oily, and volatile liquid, which has been employed with advantage in bronchitis and other respiratory affections by the simple plan of inhaling a small quantity of it placed upon a handkerchief. About one-third of it consists of a light oil, boiling at 80° to 81°C., which is the pleasing fragrant portion. The rest distils at approximately the same point as wood creasote oil. Karswood creasote is one of the pleasantest volatile antiseptics that has come under our observation, and is doubtless very suitable, as it is very agreeable, for the purposes of inhalation. It therefore deserves to be more widely known.

CABINET WHISKY.

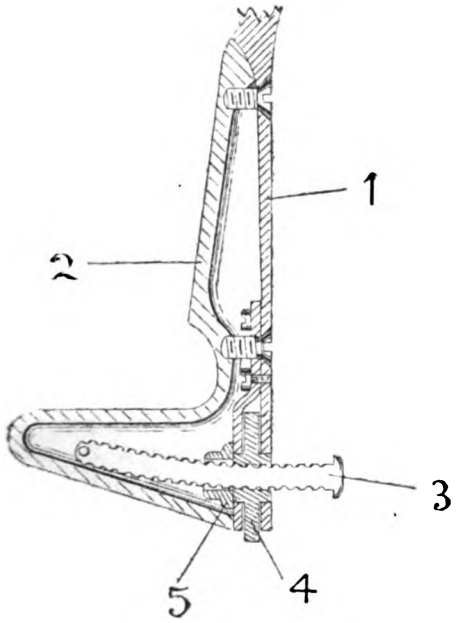
(CHAS. BLUNDELL AND CO., 63, QUEEN VICTORIA-STREET, E.C.)

The taste as well as the results of analysis of this spirit were alike favourable in respect to its quality. It is well matured and soft to the palate. On expelling the alcohol by distillation the residual liquid developed a marked aromatic smell characteristic of the resinous constituents of wood. "Cabinet Whisky" is stored, it is said, for eight years before it is placed upon the market, which step, combined with evident skill in blending, is the chief factor in producing a pure and wholesome spirit. On analysis the following results were obtained: alcohol, by weight 39·80 per cent., by volume 47·13 per cent.; proof spirit, 82·59 per cent.; extractives (due chiefly to storage), 0·59 per cent.; mineral matter, *nil*; total acidity, reckoned as acetic acid, 0·03 per cent. Its freedom from acidity is noteworthy.

PEPTENZYME.

(NEW YORK: REED AND CARNRICK; LONDON: THE PEPTENZYME CO., 25, ALFRED-PLACE, S.W.)

Apart from containing the proteolytic ferments, this interesting preparation may claim also to belong to that important class of bodies of organic extractives, like the extract of thyroid, for example, which have come into use so prominently of late in the treatment of disease. In a description of its properties and preparation it is stated that "1000 each of the following glands are taken:—the salivary, peptic, and pancreatic, Lieberkühn's and Brunner's, and the ferment extract of 1000 spleens and livers, so that peptenzyme contains a proportional quantity of the enzyme principles of the whole series of digestive organs, and acts as the secretions of the natural organs in life, since they have not been injured during the process of isolation." To one part of this "isolated protoplasmic, active ferment and latent enzyme" in the form of powder, which is slightly benzoated, 1½ pts. of powdered sugar, 1½ pts. of milk sugar, and ¼ pt. of citric acid are added. We were able in our laboratory experiments to confirm its proteolytic activity, both in alkaline and acid media; of the results of its practical administration, however, we cannot here speak. Mr. Carnrick describes peptenzyme, the preparation of which is his own discovery, as a combination of the active ferments and *undeveloped* enzymes of all the digestive organs or glands in the same physiological condition as they exist in nature and in all stages of development. Further, the process of preparing it is a "mechanical one, whereby the digestive organs immediately on being taken from the animal are freed from fat, water, and fleshy tissues by machinery, carefully dried, powdered, and sifted, and the digestive cells preserved and mixed in the same proportion and in exactly the same state of development as they existed at the moment the animal was slaughtered." Again: "It must be borne in mind that the most important contents of the digestive organs or glands is the delicate mother-enzyme principle that has not reached an active state of development." "This consists first of the requisite protoplasmic material, selected from the blood by affinity and in various stages of development, reaching at last the mature ferment and capable of changing food into the assimilable form." The cells and protoplasm in "peptenzyme," being in a dry state, with their structure and plasmic material uninjured, are said to retain their vitality unimpaired. Peptenzyme claims to be a distinct advance on compounds which are merely peptonising. It may be procured in the form of tablet, powder, or elixir.



New Inventions.

A NEW ADJUSTABLE LOCK FOR OBSTETRIC FORCEPS.

THE lock consists of a flat racked bar (depicted in the figure at 3) which can be propelled from one handle (2) to the other by turning a small wheel through the centre of which the bar passes. The wheel is inserted in the handle, and the hole in its centre through which the bar passes is a screw. The bar, by the continued action of the wheel, can be made to pass to and enter an oblong opening in a similar wheel (4) inserted in the opposite handle, and by a half-turn of the wheel the head of the bar, which is also an oblong, can be there retained. When not in use the bar can be screwed into a

Digitized by Google

hollow in the handle. The alteration Mr. E. MacWilliam Bourke makes in the forceps is merely extending the end of the handles about one inch to allow of the bar being retained, and the insertion of a small wheel in each, which projects just sufficiently to allow of its being turned by the finger and thumb. By the use of the bar compression can be

regulated and also a perfect lock obtained which can be freed by a half-turn of the wheel which is inserted in the opposite handle to that from which the bar projects. The lock can be put on any existing forceps, it does not interfere with its balance, and its cost is very slight. Mr. Bourke's idea has been carried out by Messrs. Arnold and Sons, West Smithfield, from whom the forceps may be obtained.

RIVER POLLUTION IN LANCASHIRE AND CHESHIRE.

MANY of the rivers of Lancashire and Cheshire—notably the Irwell and Mersey, with almost the whole of their tributaries, and the lower portions of the Ribble, with, more especially, the Calder falling into it at Whalley Abbey—have been the receptacles of sewage filth and manufacturing refuse for so long that the prospect of material improvement has appeared hopeless. Now, however, the outlook, though far from brilliant, is somewhat less depressing, as more energy is being displayed by the various authorities. The Ribble, one of the most beautiful of northern streams and dearly loved by anglers of all degrees, has suffered much from pollution, which has caused from time to time great destruction of fish life. The loss of the money value of the trout, salmon, and other fish is the least of the evils attending this destruction, and is a trifle compared to the interference with a pleasurable and healthful recreation, with the various trades and occupations dependent thereon, and also with the injury to the amenities of life resulting from the degradation of what should be one of the most beautiful and charming elements of scenery to the condition of a disgusting and evil-smelling sewer. But those who still cherish the hope for better things have been encouraged by the issue of a recent action by the Ribble Joint Committee against the Accrington and Church Sewerage Board for polluting two tributaries, one being the River Calder. In December, 1893, the board was ordered to adopt within eighteen months means for stopping the pollution, but nothing was done. The Ribble committee proved that for twenty-eight days from June 12th last "the defendants had made default in complying with the requirements of the order of the court." One of the "strategical proceedings" of recalcitrant authorities seems to be what is called experimenting. The analytical chemist to the Accrington board had been experimenting as to the best precipitant, at a cost in chemicals of from £50 to £300 per annum, and a member of the sewerage board was stated by a witness to have said at a meeting: "While we are experimenting we are delaying, and that is what we want." It also came out in evidence that another member had said: "I believe we have more to gain by delaying than by hurrying." The judge said there had been unjustifiable delay. "The carrying out of the Act was very unpopular, because it affected very little the persons called on to spend money in purifying the effluent—the sewage ran down the river and poisoned someone else." This being the first case "he would impose a penalty of £10 a day, making £280, with costs on the higher scale." The full penalty is £50 per day. The joint committee of the Mersey and Irwell and the Manchester corporation are in a somewhat peculiar relation. Both bodies are anxious for the purification of the Irwell above Manchester and Salford, but the committee wants more energy shown in dealing with the sewage of these cities themselves and a better effluent from them. The filthy condition of the Irwell has been patiently endured for many years, but since the completion of the Ship Canal the evil consequences of its continued pollution have been more keenly realised. From the most distant parts of the watershed it increases steadily as Manchester and Salford are approached, and the same may be said as regards the Mersey down to its junction with the Irwell. It must be admitted that Salford, notwithstanding her shortcomings, has for years past endeavoured to bring the law to bear on the various authorities above, though with little effect. Manchester has not done much to help in the matter, not so much, perhaps, from want of will as from the fact that Salford stood in the position of conservator. But however virtuous their attitude towards the delinquents above, they have both been guilty as to their own treatment of the river in its fetid and sinuous course through their midst. At the last meeting of the joint committee it was stated in a report on the sewage works at Davyhulme that nothing had been heard from the corporation since Jan. 28th as to the progress made towards their completion, and it was recommended that the corporation be requested "to furnish the joint committee before the next meeting with a definite statement as to how they intend to deal with the whole sewage of the city." There seems to have been some feeling that Manchester had been treated too leniently, and it was asked why the corporation had not been prosecuted. The answer was that there were two prosecutions pending, one in respect of Gore Brook, Gorton, and the other of Holt Town. The vice-chairman of the joint committee (who for a considerable period has been practically chairman owing to Sir J. F. Hibbert being, till the election, fully occupied with his parliamentary duties) is also chairman of the rivers committee of the city council, which has charge of the sewage of the city, so that he is the occupant of two stools on which it must be difficult to sit comfortably at once, and between which it is possible to slip. He pleaded that the corporation were bound to pay some regard to the ratepayers' pockets, that they had already spent £500,000 on this work, and that "if the land scheme of the corporation were carried out in its integrity it would mean another £100,000 on the debt of Manchester." In the end it was decided to allow two months to the corporation in which to submit their report. The case of the Gore Brook was down for hearing at the City Police-court on the 31st ult., but was adjourned for two months, as plans and estimates were being prepared for the works, "with a view of obtaining borrowing powers and the sanction of the Local Government Board in order to let the contract at once." While these proceedings show activity on the part of the authorities, it is scarcely surprising that they are not popular with some of the manufacturers, and from time to time letters appear protesting against interference with the long-established practice of fouling the streams for the benefit of neighbours lower down. Happily it is not always so, and testimony has often been borne in the committee to the generous and hearty coöperation of many of the manufacturers themselves in the efforts being made to bring back the rivers to a more cleanly and wholesome condition.

THE LANCET.

LONDON: SATURDAY, AUGUST 17, 1895.

OUR columns have again been opened to the discussion of the several questions which arise out of the fact that the prefix of Doctor is both a correct academic appellative and a colloquial method of address. The ambiguous position of the title has bred, as was natural, many ambiguities, so that there are points and half-points without number over which differences of opinion will prevail, and consequent dispute can take place. This is well illustrated by the letters received by us, a typical selection of which have been printed, and we may say at once that we do not intend to deal seriatim with the issues therein raised. We intend to use them as a text for an exposition of our views on the question, premising that these views have been adopted by us more with an eye to courtesy and practical expediency than to cold logic, which can have little part in anything which starts with a flaring ambiguity.

Firstly, there can be no doubt that in all circumstances where medical status has a claim on professional or public attention, in all official connexions—whether exclusively medical or no, and in the social relations of strictly medical circles, only one class of practitioner has a clear and incontrovertible right to the title of Doctor—viz., the Doctors of Medicine of those universities whose doctorates are registrable degrees. It would be strictly logical counsel to advise that only the persons possessing this clear and incontrovertible right should be addressed as Doctor, but as we ourselves, in a medical journal, have decided that such a counsel is too much one of perfection in a world of necessary compromise for us to rigidly follow, we cannot consistently urge the necessity of the strict limitation upon our readers and upon the numerous correspondents who have asked us for a pronouncement. There are undoubtedly cases where the withholding of the title, while strictly correct, constitutes an ungracious act of omission. In the case, for instance, of a man who is registered by the General Medical Council as holding the diplomas of recognised licensing bodies, and who adds to these the doctorate of a university of whose status as a degree-granting institution there can be no doubt, although not registrable—in such a case we consider the frailty of addressing the practitioner as Doctor so venial that we lapse into it as a habit. It will be noticed that the error, though we hope pardonable, brings with it its own risk of punishment, for it might entail at any moment the invidious task of defining the status of a given university. This in some cases would be easy, but in some might require an amount of discrimination that could not be provided for by rules; and then the situation would have to be dealt with by every man according to his private taste. Again, to give a second very obvious example where the withholding of the title of Doctor causes the precisian so doing to assume a somewhat awkwardly exclusive attitude, there is the case of Bachelors of Medicine, whose baccalaureates are held from universities granting a duly registrable doctorate. Should these gentlemen be addressed as Doctor? We ourselves give them the title, knowing that to do so is indefensible logically, but finding that not to do so to *some* would entail serious confusion, and that, as a consequence, not to do so to *all* would have the appearance of a no less serious lack of courtesy. There have been Bachelors of Medicine who have held the highest posts at general hospitals or in the great medical corporations without proceeding to the doctorate. Such Bachelors of Medicine have been, and are still, considered eligible to apply for the staff appointments at public institutions, whose honorary physicians are so universally styled Doctors, and have been styled Doctors for so long a period, that to do otherwise would require, in our eyes, a more practical justification than an attempt, however laudable, after accuracy in terminology. We cannot admit that the question of the comparative difficulty of the examinations of certain of the universities and certain of the corporations affects the procedure. While the period between the securing of the baccalaureate and the advance to the doctorate is unlimited in length by the universities, and while strictly medical circles recognise the Bachelor of Medicine of all the degree-granting universities as a proper competitor against the Doctor of Medicine for medical appointments and awards, so long will it be a task too hard for us to abstain from illogically conferring the title of Doctor upon the Bachelor of Medicine; and we cannot attempt to separate the Bachelors of different universities into groups requiring different treatment, although the gulf placed by some—London University, for instance—between the baccalaureate and the doctorate is a sensible obstacle, while that in others forms no practical impediment.

The position of the diplomates of the several Royal colleges and corporations is so universally recognised (and also, we are pleased to say, so universally acquiesced in by themselves) that it may seem over-explanation of the obvious to refer to it; but there are one or two little points even here that, from the frequency with which they are referred to us for our opinion, would seem to require elucidation. Firstly, such diplomates are not entitled to the style of Doctor however well known to their patients they may be under that style. The diplomate must not arrogate to himself a title conferred upon him colloquially and not gained academically. The profession, knowing well that degrees do not make a man, and the public knowing it almost as well and daily learning to know it better, he will suffer nothing by his abstention; and this we are glad to remember, as undoubtedly there are degrees obtained by many university graduates whose professional attainments are in no way superior to those of the diplomates of the Conjoint Board, and whose preliminary testing has neither been so severe or so thorough as many of their fellow-students to whom circumstances have made the rightful possession of the title of Doctor almost an impossibility. Secondly, the holder of the Licence of the Society of Apothecaries of London is not entitled to be called Doctor; the fact that the Licence constitutes in itself a double qualification not being relevant to the question. Thirdly, the holder of diplomas from any

Digitized by Google

corporation who happens to be a Doctor of some other faculty than medicine in any university—it makes no difference whether the medical doctorate of the university is recognised by the General Medical Council or not—is not entitled to be addressed as Doctor in medical circles. We cannot, while treating the subject in a general manner, take up all the special points that have been laid before our readers in the recent correspondence. Nor can we furnish a ready-made opinion to fit the many cases that will assuredly be submitted to us in the future as they have been in the past. We have only taken advantage of the fact that as many communications on this ever-green topic have lately been before our readers the subject must be in their minds, and the opportunity for explaining our procedure is therefore advantageous. We do not claim to be, or to have been, strictly logical in this procedure, but we consider that circumstances prevent the strictly logical method of limiting the use of the title from being quite fair or quite convenient.

THE complex conditions of modern working life make the absolute need of a holiday more apparent every year. In all classes of life, from Emperors down to the humblest workers, we do as much in a week as our forefathers were accustomed to do in six months, and the need for recuperation is, therefore, so much the greater, and fortunately the means for supplying this need have grown coincidently with it. The enormous increase in facilities of locomotion which is a notable characteristic of the present day enables even those of moderate means to go far afield; neither can there be any doubt that a complete change of air, scenery, and surroundings is a very powerful factor for good in the treatment of those wearied with work of whatsoever kind. The days are gone when Islington was really "merry" and had fields, when the fisherman could walk to Tottenham and find a clear Lea to exercise his craft upon. There are still left a few places within twenty miles of London which are really country, and not given up to the builder, jerry or otherwise; but the majority of holiday makers go either to the seaside or on the Continent, and it is this kind of holiday that we propose more particularly to consider now.

It may be well asked, "Do those who go for a holiday set about it in the majority of cases in the right way?" and the answer in general is "No." First of all comes the family conclave assembled to decide upon the important question of where to go, which generally ends in the selection of some place favoured by the younger male members of the family. And here we may point out that when people live together all the year round it is the greatest mistake for them to attempt to take a holiday together. The true holiday implies much more than going away from home; it means rest, change of company, being taken out of oneself—this last item is perhaps the most valuable of all. We will suppose, then, that the holiday maker has settled the matter to his or her satisfaction and has started with a friend. Let him beware of the other great mistake so constantly committed—that of trying to do too much. To rush from one town to another; to "do" the Ardennes, Cologne, the Rhine, Nuremburg, perhaps Bayreuth, Styria, and more or less of Italy in six weeks is not a holiday but a penance, and yet there are those who do this and think that thereby they are laying up a store of health for their return to work. The true holiday consists, not in doing nothing, but in having nothing to do—it is the sense of freedom, the feeling that one can go on or stop, whichever is most convenient. Trains and the catching of them, the baleful superstition that "objects of interest" must be visited and inspected, the hurrying from one hotel to another, all these mar the rest which is sought. Then, too, there is the question of climate. We are convinced that the general rule which is followed of going south for the winter—unless, indeed, Egypt or some similar place be selected—is wrong. The countries to go to in winter are those where winter is a reality, and where means are and can be taken to meet it. Russia, Norway, and Sweden are seen at their best in winter, and the beauty of a northern winter night is inconceivable to those who have not seen it, while the dry, windless, cold atmosphere braces every tissue of the body, and if the cold begins to be felt too much the houses are really warm, and warm throughout. Compare this with a shivering day on the Riviera where the art of keeping houses warm is unknown. The same argument will apply to summer. If a warm country is selected the house, the food, and the style of clothing will be found in keeping. In the variable climate with which we are favoured we can neither prepare for winters like the last nor summers like that of 1893; but at least, when we can go to a country blessed with climatic regularity let us visit it at the most favourable time.

The true holiday, then, is not such an easy matter to obtain as it seems at first sight. A congenial companion, a determination not to try to crowd too much into a short space of time, a discriminating selection in the matter of place and distance, and for most places some knowledge of their history, whether political or natural, will go far to make a holiday what it really should be—a complete rest not only for the body, but, what is perhaps more important, for the mind also; and if certain discomforts are met with—and they very generally are—we may remember the words of an old writer: "Nothing would be more tedious than to be glutted with perpetual jollities; were the body tied to one dish always, though of the most exquisite delicacy that it could make choice of, yet after a time it would complain of loathing and satiety. Discontents are sometimes the better part of our life. I know not well which is the more useful; joy I may chuse for pleasure, but adversities are the best for profit. And sometimes these do so far help me as I should without them want much of the joy I have."

THOSE who desire that due instruction in the rules of professional conduct should not be omitted in medical schools will be pleased to read the admirable address on Medical Ethics by Professor GREENFIELD, delivered to the new graduates of the Edinburgh University and published in our present issue. It will well repay perusal by all who wish to guide their conduct on principle and to uphold the reputation of the profession. He makes a point of assuring the young graduates that they are not "mere licentiates of a medical corporation," but members of a university which in the past has been, as he trusts it will be in the future,

Digitized by Google

distinguished in all branches of learning. The distinction drawn by Professor GREENFIELD is perhaps capable of being considered somewhat invidious, and we have no intention of endeavouring to appraise the relative merits of universities and corporations. There is, however, one point in which the corporations undoubtedly show to advantage in comparison with the universities, and that is in respect of the question of medical conduct. The corporations sometimes administer discipline to their members, even to the measure of excommunication. If the members violate the regulations of a corporation in the matter of professional ethics they are rebuked, and if they do not repent they are deprived of their diplomas and removed from the roll of membership. Most of the universities have no such powers over their graduates, and some of them do not seem to wish to have them. "Once a graduate always a graduate" is their doctrine. Graduates are, according to this view, the only class to whom the punishment of degradation must not be applied Fortunately, the doctrine is breaking down, and some of the universities are, in fact, seeking the powers wherewith to rid themselves of those graduates who act unworthily of their gowns, and to place themselves in this regard on a level with the corporations. We would remind those universities which do not seem too keen to acquire such powers that if they wish the profession and the public to regard their graduates as "more than mere licentiates of corporations" they must act accordingly and be prepared, if necessary, to degrade those whom they have graduated.

We must pass hastily over Professor GREENFIELD'S interesting and just remarks on the happy relations which subsist between the town and University of Edinburgh. It was not perhaps, always so. There was a time when the town council had too much patronage in its hands, though to its honour the professors it chose were often men of the widest renown; but now nothing can be more satisfactory than the pride of the Fathers of the city in the university, and their coöperation with its authorities in maintaining its high prestige. Coming to the main points in the address, we may enumerate them broadly in the following way. Cultivate a high ideal of professional life and its objects; respect the confidences of the profession; consider how to convey truth to patients and their friends; remember that sickness makes a man not himself—"the higher his intelligence the greater his activity, the wider his responsibilities the more intolerable to him is sickness," as involving not so much physical pain as mental, and the suffering of others dependent on him; have patience under such circumstances with peevishness and cultivate calmness, cheerfulness, and sympathy in connexion with clearness, decision, and thoroughness in directions and candour in speech. Like all good moralists, Professor GREENFIELD had to fall back on the Scripture and say, "We that are strong ought to bear the infirmities of the weak," and to quote several other texts from the same indispensable source. While vindicating the perfect freedom of patients to choose their own medical man, he was emphatic in reminding his hearers that "one of the most stringent and primary rules is that no medical man should under any guise, directly or indirectly, interfere with the conduct of a case which is under the care of another unless consulted by him." He denounced all tendency to comment on the treatment and diagnosis of others, insisting that no man can judge of a case he has not seen. At the same time he discouraged all local jealousies and distrusts of professional neighbours. He remarked that he had often been astonished that patients had not enjoyed the advantage of consultation with medical men in their own neighbourhood, and found the explanation in mutual distrust. He enjoined on his hearers the duty of thoroughness in investigating cases, observing most truly that more mistakes are made by want of thoroughness than by ignorance. Finally, he ended with a word of cheer to those who had been backward in class and college distinction, reminding his hearers that it is not always the brilliant students who become distinguished in after-life.

These are thoughtful words and cover more than may appear at first glance. There is a disposition at present to correct the evils of the profession by legislation and by the disciplinary action of the medical authorities. There is need of these; but, after all, the strength of the profession and its place in public estimation will depend on faithfulness to its own traditions, to its great unwritten laws, to its highest morals. Reverence for patients, respect for their feelings as well as for their health, will make us adepts in the investigation and treatment of their cases and in the art of telling them all the truth that can do them good or is consistent with our main duty—that of prolonging their lives. It will make us honourably reticent of all family and personal facts which we come to know professionally. Reverence for professional neighbours will make us charitable in our judgments of them and quick to see in each of them a brother rather than a rival. Reverence for ourselves will make us less discouraged by the vicissitudes of practice and more incapable of all mean methods towards success.

Annotations.

"Ne quid nimis."

SMALL-POX AND THE ROYAL COMMISSION ON VACCINATION.

THE existing prevalence of small-pox in the metropolis acquires additional importance, not only because it has appeared at a time of the year when small-pox is, as a rule, least likely to become epidemic, but because at no time within the present generation has there been so much tendency to disregard the law as to vaccination. This latter condition of affairs has been brought about by the extraordinary delay in the issue of the report of the Royal Commission on Vaccination which was appointed in August, 1889. We do not doubt that the preparation of all the evidence which has been brought before the Commission, both by witnesses and by subcommissioners of their own appointing, must take a considerable time, but it is absolutely impossible that the minds of the Commissioners should not be made up as to the various points which were submitted to them when they were appointed; and we see no reason why Parliament should not request the report forthwith, leaving the question of evidence to stand over, as was done in the case of the Royal Commission on Tuberculosis. In one

Digitized by Google

sense, Parliament may not have the authority to make such a demand to a Royal Commission, but Her Majesty's Ministers can make it; and having regard to the present position of affairs the strongest possible pressure should be put upon the Commission to hand in their report before they scatter for their holidays. Even after it has been received there will be quite sufficient delay in determining as to the administrative and other details for giving effect to any recommendations they may make as to alterations in the law or in the methods of performing vaccination. But what the public now want is an authoritative statement as to whether vaccination does or does not afford a protection against small-pox and whether the operation ought to be adopted and carried out with a view to such protection. We can conceive of no reason for delay in making such a statement; and it is the more imperative that an announcement as to this should now be made, since boards of guardians are constantly declaring that they are awaiting it before deciding whether to enforce the provisions of the Vaccination Acts or not. And in the meantime a population is growing up which is not vaccinated, and small-pox is spreading in our midst. We regard the immediate position of affairs as involving much gravity. If small-pox gets a hold on London before autumn it will be a very serious matter both for London and for the provinces; for anything like an epidemic in London has almost always been succeeded by the extension of the disease into provincial towns and districts. Whilst, therefore, we are quite ready to acknowledge the extent of the task which the Royal Commission have had to perform, we cannot refrain from pointing out, first, that they have had ample time to come to a decision on the material laid before them; and, secondly, that the present emergency is one that admits of no further delay in letting the public know what conclusions they have arrived at on the principal matters submitted to them.

SUGGESTION AND CRIME.

A RECENT murder in England elicited, on the trial of its perpetrators, a solemn admonition addressed by the Court to the purveyors of juvenile literature in which the robber and the assassin are presented in an attractive rather than deterrent light. The jury, indeed, saw a distinct nexus between the perusal of such literature and the crime of the young prisoners in the dock. Their finding has been much quoted abroad, more than one Continental journal approving of its tenour and recommending a similar admonition on the part of tribunals sitting in judgment on delinquents of tender years. In Switzerland the Société des Médecins et Pharmaciens of Berne, at a recent sitting on the prevalence of self-murder, came unanimously to the following decision: "For twenty years the average of suicides in Switzerland has been 650, a proportion exceeded only in Saxony and Denmark. It has, besides, been matter of common observation in our great cities, at longer or shorter intervals, that a certain number of suicides succeed each other *coup sur coup*—suicides in which the first case often acts by way of suggestion, inciting individuals predisposed to commit the same desperate act. It is therefore to be desired that in future the daily press should refrain from reporting cases of suicide. This resolution will be brought under the cognisance of the Swiss Press Association." One of the leading organs of the Confederation, the *Journal de Genève*, comments favourably on this resolution of its medical *confrères*, and, with perfect justice, we believe, claims credit to itself for having studiously and steadily excluded from its *chronique* all cases of suicide committed within the canton. The policy thus recommended and acted upon has its warrant not only from experience, but even *a priori* from the study of psychology. The mimetic principle in man, particularly in those developments in which evolution sees a distinct retrogression to a lower, more animal type, has its roots deep down in the organisation, mental as well as physical, arguing a pithecoid strain which only awaits certain favouring conditions to manifest itself unmistakably in character. The epidemic of suicide which has been so much remarked of late has had its counterpart in the epidemics of murder or manslaughter so apt to culminate in great social upheavals like that of the French Revolution or of the Parisian Commune in 1871. Lethal violence on both occasions was "in the air," and what Zola calls the "homme-bête" became a ready imitator of "what the rest were doing," in other words, a "mission of massacre." We have small belief that such admonitions as those of British tribunals or foreign professional associations will have much practical force on contemporary crime, favoured as it notoriously is by fanatical estimates of the worthlessness of human life almost openly avowed. But neither law nor medicine need be deterred from throwing its influence into the scale of social and mental sanity by the dread of having its "opinions" set down as merely "pious" or relegated to the limbo of the "academic."

INDIAN PILGRIMS AND CHOLERA.

A BILL was introduced by Sir Alexander Mackenzie at a meeting of the Supreme Legislative Council of India on the 11th of last month for the regulation of pilgrim ships. The Bill is in the main the outcome of the recommendations of the Paris cholera conference of last year, and the new regulations will be put in force before the next pilgrim season. The Government of India has in this matter acted out of deference to public opinion and has done its best to meet the recommendations of the conference, and we understand that it may confidently anticipate the reception of strong representations from the Mahomedan community in India as to the serious increase of the cost of pilgrimage which will be entailed by some of the provisions contained in this new Pilgrim Ships Bill. We think that the Government of India is therefore in a position to demand that something should now be done by the Ottoman authorities on their part in regard to Kameran and the proper protection of the pilgrims at that place. The *Times of India*, in a recent article on Kameran and the Pilgrim Traffic, alleges that while, on the one hand, little or no evidence can be adduced in support of the theory that cholera epidemics at Kameran and the Holy Cities have been originated by sea-borne pilgrims importing the disease from India, there is ample evidence, on the other hand, that the enforced detention of the pilgrims on that island has the most injurious effects on their health, and that Kameran is itself a cholera-infected depôt and a sort of hotbed for the development of that disease, whether we regard it as endemic at that station or as an importation from India. Our Indian contemporary gives a full topographical description of the island of Kameran, of the lazaretto with its seven quarantine camps, of the so-called sanitary arrangements, and of the disinfection and other methods of procedure pursued in connexion with the unhappy pilgrims during their enforced detention there, and declares that the whole quarantine process is a delusion and that no precautions whatever are taken as regards the pilgrims' water and food supplies. The importance of the question is as great to India as it is to Europe. Thousands of pilgrims make a long and perilous journey at a heavy cost and great sacrifice to themselves for religious considerations which are to them of an imperative kind. If they do not actually die from cholera contracted at Kameran they are liable to be sent back to India in an enfeebled state of health after an enforced and long detention, with their mission unfulfilled and their means exhausted. We quite concur with the

Digitized by Google

Times of India in thinking that common humanity, as well as the safety of Europe, demands that England should take up this question, and that the British Government should adopt some definite line of action in regard to it. Kameran is, in its present condition at any rate, an unfit place for a quarantine station; there should be an International Board of Health in the place of the present ineffective Ottoman Board, and in justice to our Indian Mussulman subjects and in return for the efforts which the Indian Government has made to meet the wishes of the Paris conference the treatment accorded to the Hajis from India at Kameran, Jeddah, and in the Arabian desert requires to be thoroughly investigated and reformed. It is as important in its way as the question of Armenia, and it may be urged upon the Sultan on the ground of protecting and safeguarding himself and his subjects in Constantinople and Turkey from epidemic cholera, about which he is known to be keenly interested.

AN ALLEGED CASE OF POISONING BY ARSENIC AT SYDNEY.

A TRIAL that is probably unique in the history of legal procedure has just been concluded in Sydney, and the case presented not only features which have aroused the most intense public interest, but also points of medico-legal importance. The evidence given has been most voluminous, and in many points is contradictory. It would be impossible to summarise it all, but briefly the main facts appear to be these. Early in March last a man named George Dean was accused at the North Shore Police-court, Sydney, of attempting to poison his wife. He was committed for trial, and the case was heard at the Central Criminal Court by Mr. Justice Windeyer and a jury in the beginning of April. The jury took some time to consider their verdict, and the judge told them there could be no doubt about the guilt of the prisoner. The jury then returned a verdict of Guilty, with a strong recommendation to mercy. The judge pronounced sentence of death. Popular feeling was roused in favour of the prisoner, public meetings were held, and the sentence was appealed against and commuted to imprisonment for life. The agitation in favour of the prisoner continued, and a petition was presented to Parliament for the appointment of a Royal Commission to make full inquiry into the case. The Government then appointed a Royal Commission, consisting of Mr. F. E. Rogers, Q.C. (chairman), Dr. F. N. Manning, and Dr. P. Sydney Jones. From the evidence given at the trials and before the Commission it would appear that a few days after her confinement Mrs. Dean complained of restlessness and sleeplessness due to neuralgia. Her medical attendant, Mr. Newmarch, prescribed a morphine mixture. She was then attacked with vomiting, which he attributed to the medicine. This was in the first week of January. On March 4th, when he saw her again, she was suffering from vomiting and purging. Her temperature was subnormal. He attributed the attack to something she had eaten. The same evening a bottle containing some lemon syrup was brought to him in a mysterious fashion, and he was asked to get it analysed. It was then suggested that Dean was poisoning his wife. The syrup was analysed and found to contain 1¼ grains of arsenic and 1½ grains of strychnine. On the 10th Mr. Newmarch cut a fæcal stain out of Mrs. Dean's night-dress and had it analysed. It contained traces of arsenic. During and subsequently to the trial at the Criminal Court Mrs. Dean developed peripheral neuritis. No satisfactory evidence was given as to where the poison was obtained or to connect any person with its purchase, and the only evidence to connect Dean with the poisoning was that of his wife and her mother, to the effect that they had seen him mix a powder with some of the medicine, and that he prepared and gave her all her food and medicine, and that tea and groats and other articles of food given her by Dean had a bitter taste. Mr. Newmarch and the medical men who subsequently attended Mrs. Dean at the hospital had no doubt that she had suffered from arsenical poisoning, though the defence suggested that the symptoms might have been due to influenza. A great deal of medical evidence was given on this question and as to the effects of arsenic, and especially as to the effects of arsenic combined with strychnine, and statements were made that the two drugs were antidotal to each other. Dean had previously borne an exemplary character, but evidence was given to the Commission that in his youth he had been in gaol. Evidence was also given that Mrs. Seymour (Mrs. Dean's mother) had been a notoriously bad character, had kept a shop which was practically a house of ill fame, and had been the associate of criminals. The main defence was that there was no evidence to show that Dean poisoned his wife except that of his wife and mother-in-law, and that there was a conspiracy on the part of the mother and daughter to accuse Dean of the crime and so get rid of him. The Commission was not unanimous in its report. Mr. Rogers, the only legal member, upheld the decision of the jury and the opinion of Judge Windeyer that Dean's guilt was not open to question. The two medical members reported that there was doubt whether he administered the poison and recommended that he be released, and released he has been accordingly. We are not aware of any previous occasion upon which the decision of legal authorities on matters of evidence has been reversed on the recommendation of medical men.

THE ALLEGED INCREASE OF INSANITY.

IT is eminently satisfactory that the Lunacy Commissioners are beginning to recognise the importance of age incidence in the consideration of the statistics of insanity with a view to the determination of the problem whether the constant increase in the number of the insane under treatment in England and Wales really signifies an increasing prevalence of lunacy, or rather of occurring cases of insanity. In their recent annual reports it is true that the Commissioners have constantly expressed their opinion that the large increase in the number of known lunatics is mainly due to causes other than an increase in the prevalence of insanity as an active disease. They have, however, until now turned a deaf ear to the urgent appeal for statistics of the ages of the patients annually admitted to the lunatic asylums, and of the ages of the patients who die year by year in those asylums. We are glad to note in the recently issued report a first instalment of such age statistics, which, if continued for a series of years, and if amplified, will in a few years afford the means for throwing much light upon this important and interesting problem. It is pointed out that in recent years there has been a marked increase in the number and proportion of admitted cases of "mental decay resulting solely from old age." In proof of this the Commissioners show that in 1883 the admissions to asylums of persons aged upwards of sixty years were equal to 12·5 per cent. of the total admissions; in 1888 this proportion had increased to 13·2 per cent.; and in 1893 it had further increased to 14·7 per cent. These statistics are based upon information contained in the annual reports issued by county and borough asylums, and conclusively prove that the cases admitted above the age of sixty years have increased at a far more rapid rate than the admissions under that age. These cases represent, probably, to a large extent transfers from workhouses to asylums, but from whatever cause the increase arises it can scarcely be seriously asserted that this increase of cases of senile mental decay represents an increase of true insanity. These figures, moreover, throw some light

Digitized by Google

upon the age incidence of the persons returned in England and Wales as mentally deranged at the three Censuses in 1871, 1881, and 1891. The ratio per 1000 of the English population returned as mentally deranged under the age of forty-five years was 2·24 in 1871, 2·29 in 1881, and 2·26 in 1891. Thus the ratio of insanity to population at these ages remained practically stationary during this period of twenty years. Above the age of forty-five years, however, the calculation of the ratio of insanity gives very different results; the ratio was 6·35 per 1000 in 1871, 7·40 in 1881, and 8·02 in 1891. In the absence of information as to the ages of cases admitted to asylums it was impossible to ascertain how much of this increased incidence of mental derangement upon elderly persons was due to what may correctly be called the accumulation of cases caused by improved treatment of the insane in asylums, and how much to an increase in the number of admissions of cases of senile dementia. The figures given in the Lunacy Commissioners' last report established beyond doubt the steady increase, both actual and relative, in the admission of cases of so-called insanity above the age of sixty years. The important bearing of these figures in the direction of disproving the reality of the alleged increase of insanity in this country will, it may be hoped, induce the Commissioners to give more complete statistics of the ages of the annual admissions to all asylums for the insane in future reports.

ABDOMINAL SECTION FOR PUERPERAL SEPTICÆMIA.

THE July number of the *American Journal of Obstetrics* contains an interesting communication by Dr. J. M. Baldy on Abdominal Section in Certain Cases of Puerperal Septicæmia. He distinguishes between cases in which there is suppuration and cases where there is infection of the Fallopian tube, the ovary, and possibly of the peritoneum without any formation of pus, but with exudation recognisable by physical examination. A case is given as an example of the former class in which a patient was very ill after delivery for several weeks, the uterus was subinvoluted, and to the left side of it could be felt a large, boggy mass firmly adherent, tortuous, and tender. An abdominal section was performed, and the swelling, which proved to be the left Fallopian tube and ovary distended with pus, was removed, the patient making a rapid recovery. So far there is nothing remarkable in Dr. Baldy's paper. It is well known that ovarian tumours, which may or may not be suppurating, are frequently noticed for the first time during the lying-in period owing to the size of the abdomen remaining greater than is normal after delivery, and the proper line of treatment for such tumours within a few weeks of delivery is the same as at other times. In the second group of cases, where there is no pus, though exudation can be felt and the patient is acutely ill, Dr. Baldy admits that it is clinically a most difficult matter to decide whether or not pus is present, but if the opinion be come to that there is no pus then no operation is indicated. In cases of general purulent peritonitis, from any cause whatever, Dr. Baldy does not believe that any line of treatment, operative or other, has ever saved the patient; but, inasmuch as a diagnosis of general peritonitis may sometimes be made when really the peritonitis is more or less localised, in doubtful cases Dr. Baldy advises operation. Turning then to the cases of puerperal septicæmia grouped as pelvic cellulitis, the question again arises as to whether there is or is not pus. Where there is not pus then as a general rule no abdominal section is likely to be required; where, however, there is pus, although it is admitted that the whole extent of infected and suppurating connective tissue cannot be removed, Dr. Baldy advises total hysterectomy, not only on account of the amount of diseased tissue so removed, but because the affected area is so thoroughly opened up by the operation, and placed in a favourable condition for drainage. So far the cases under consideration have been those of puerperal septicæmia where there is a definite swelling to be felt that may be due to either suppurating cellulitis, or to salpingitis and peritonitis, with accumulation of pus in the Fallopian tubes or ovaries. There is, however, a group of cases of puerperal fever where no swelling is to be felt in the pelvis and where absorption is taking place from the interior of the uterus itself. In this group, after trying intra-uterine douching, curetting, the application of pure carbolic acid, packing with iodoform gauze, and the like, without improvement soon appearing, Dr. Baldy also recommends abdominal hysterectomy, though here he thinks removal of the uterus as low as the internal os sufficient. He has collected nineteen cases of hysterectomy during the puerperal state performed by American operators. Twelve of the patients died and seven recovered. Dr. Baldy thinks sufficient success has been obtained to warrant a further and more general trial of abdominal hysterectomy in the special class of cases under consideration, though he admits the field for hysterectomy in puerperal cases is not a large one.

PRESCRIBING DRUGGISTS.

THE prescribing druggist is like the poor for whom he prescribes, always with us, but the latest instance reported exhibits some "features of interest" rather different to the usual run of these cases. A child named Clark, suffering from bronchitis after measles, was attended by the druggist, who gave it some harmless powder. As the child did not get better he told them to send for a medical man, which they did, but the child died. Mr. Perdue, the druggist in question, said he had attended the sick, the dying, and the bereaved for six years. He never got any fees, but he added: "I get my living by converting tea-leaves into anything. It would surprise anyone to see what I make out of tea-leaves." Mr. Perdue is evidently well within sight of the philosopher's stone. We only trust that tea is not among the things that he converts tea-leaves into, for in certain parts of London a large trade is, we believe, done in tea-leaves. They are rolled, dried, faced, and sold as fresh tea. However, this trade is less harmful than Mr. Perdue's by-occupation of prescribing, although, as the coroner said, "Anyone may prescribe at their own risk."

SUICIDE IN ITS MEDICAL AND ITS MORAL ASPECTS.

IT has been noted elsewhere that a tendency to suicide has recently been somewhat unusually prevalent. In THE LANCET of July 28th, 1894, we suggested that this tendency might be capable of partial explanation on physical grounds, and in a later issue (Aug. 11th) we published a letter by Dr. Alexander Haig bearing upon the same subject. The regular, though happily never frequent, connexion between solar heat and this form of crime has been repeatedly observed, and may, without undue straining of logical conditions, be accepted, at all events as far as it goes, as a working hypothesis founded on accurate observation. When we go further and seek to explain the hypothesis itself, however, we are still conscious of the insufficiency of our data. The theory by which Dr. Haig would associate mental depression with blood vascular tension due to uric acid is indeed helpful in its measure, as it is certainly ingenious. The measure of assistance towards a sufficient explanation is nevertheless in both cases very meagre. It is evident that in the case of most persons a wide desert of despondency intervenes between the state of mind which

Digitized by Google

corresponds to a hard pulse and overladen tissues and the last fatal folly of despair. Save in the case of insane or weak-minded persons, it is hardly possible to conceive that men can be impelled to suicide by purely physical conditions, which are, after all, so common as hardly to be regarded as abnormal except by the scientifically educated mind. We would by no means overlook the necessity of treating these cases by appropriate means, but we are none the less assured that the reckless will which induces men to convert a weariness of life into a purpose of self-destruction does not depend upon mere atmosphere or mal-excretion. Where they are free to operate, the reserves of moral sense, thought, and resolution have either been previously exhausted or have not been drawn upon. A feeling of personal loss or a morbid fear of such has obliterated the sense of human relationship. The interest of dependent or associated neighbours and of relatives is forgotten. Self-love, not social duty, is the impelling force. We have not much hope that persons in this mood will be greatly influenced by changes of weather or by purely physical treatment. We would rely more upon the full and frank assertion of the duty and utility of all human beings to each other and to the Providence essentially friendly to men which called them into being. Suicide is, after all, a moral failure, an evidence of the mastery of mistrust, an act of rebellion against the authority of patience. Obviously no drug, no social reform even, can effectually cure it, unless they be aided in the first place by a frank and full recognition of man's moral relation and responsibility.

THE CASE OF SURGEON LEA, R.N.

IT will be remembered that in an annotation in THE LANCET of June 22nd last we referred to the case of Surgeon Lea, R.N., and said that, considering his hitherto unblemished reputation, and the very unsatisfactory and incomplete nature of the evidence adduced at the court-martial held on this officer at Sydney in April last, we were decidedly of opinion that the matter called for further careful investigation by the Admiralty in this country. We are glad to learn that Surgeon Lea's case is under the consideration of the Lords of the Admiralty and the legal advisers of the Crown. The circumstances were of an altogether exceptional and curious character, and as far as we could judge from the published reports of the court-martial it seemed to us that Surgeon Lea had been hardly dealt with. We consequently await the result of the decision that will be, or has already been, arrived at with much curiosity and interest. Surgeon Lea was a distinguished student of University College Hospital, and a former pupil of the present President of the Royal College of Surgeons of England. He entered the Naval Medical Service in August, 1883, taking the first place, and has consequently twelve years' service.

FOR THE SILLY SEASON.

THE sea serpent has at last been caught, or rather cast ashore and photographed, but though associated with wild legends there has never been any reasonable doubt as to his existence. But there is a wilder form of credulity which comes up every year in the shape of stories of people who "bring up" live animals, and the following instance appears in the columns of the *Star*, which must be either extremely credulous or have a painful disregard for the truth. The story comes from Silvertown—"Ex oriente semper aliquid novi." Such stories as these always come from the East-end, and the present one is to the following effect. A lady in Silvertown had suffered from spasms, diarrhœa, and sickness for some time. Two medical men and a hospital were tried in vain. She then consulted another medical man, who, with a rapidity of diagnosis which does him infinite credit, said "By Jove, it's a worm," and proceeded to administer quinine and nitric acid. After three days of this treatment, during which the patient endured much suffering, she felt something rise in her throat, and, putting her finger and thumb down her throat, pulled off the head of a newt, which was followed a few moments later by the body and tail, eight inches in all. According to the *Star*, the medical man's explanation is that it was swallowed either in water or watercress, and the process of getting rid of it was as follows: "The acid in the quinine irritated the animal, causing it to jump about and tickle the bronchial tubes. The tickling produced the vomiting, and the vomiting produced the eft." We must confess to serious doubts as to the truth of this story. A newt eight inches long is almost unknown in England, and we think it may well be classed with the story of the bees or wasps which were vomited by a harvester in Wales some short time ago, and upon which we commented in these columns. But nothing will ever induce a certain class of patient to disbelieve in the existence of living animals inside them.

THE DIFFUSION OF SMALL-POX.

THE epidemic manifestation of small-pox through which London is at the present time passing would seem to have reached its highest point for the moment. The cases newly arising in the fourth week of July were 98 in number, and though this number gave place to 90 in the succeeding seven days the attacks coming to light last week were but little over 50, the registered deaths in the successive weeks being 1, 1, and last week 3. As might have been expected, the patients for whom the Metropolitan Asylums Board found they had to provide rapidly increased, and in the four weeks ended last Saturday were respectively 23, 115, 60, and 54; whilst the cases remaining under treatment in their hospitals and at Highgate Small-pox Hospital rose from 89 to 199 in one week, and thence to 237, and last Saturday to 273. At the last meeting of the Asylums Board the fact came out that, whereas the earlier cases were in the main from shelters and the like, the later manifestations were largely from among the resident population, a sign of deep significance as tending to show that the disease had fastened on the portion of the community permanently located in London. In these circumstances Gore Farm Hospital was cleared of its scarlet fever patients and reserved wholly for convalescent small-pox cases. The application of West Ham to be allowed to make use of the Board's accommodation was heard, and regret was expressed that the means at the disposal of the Board did not admit of its being granted. But very fortunately the disease has not made any great inroads on that borough yet, the cases in recent weeks being few in number. The deaths registered in the metropolis last week as occurring from small-pox were 2 in vaccinated adults aged over twenty years and 1 in an unvaccinated person of the like age period. Two belonged to Whitechapel and 1 to Shoreditch sanitary areas. Districts contributing cases to the hospital ships last week and during the present week were, among others, Whitechapel, Mile End, Plumstead, Lambeth, Wandsworth, Paddington, St. George's Southwark, and St. George's-in-the-East, the western and northern areas being generally free from the disease. In the home county of Essex there were, in addition to the few cases at West Ham and Leyton, some attacks at Leigh, not far from Rochford. In the Midlands there is but little to chronicle, one or two places in Staffordshire and Derbyshire being slightly affected; but westward the Salop County Council have had before them the history of an outbreak of a localised character at Oswestry, traceable to a case found at a common lodging-house,

Digitized by Google

Subsequently 5 other persons residing in the same house were found to be suffering from the disease, as was an innkeeper's wife, infected probably by the original case, the patient having conversed with her in the inn. Measures of disinfection have been taken, and persons likely to have been in danger of infection have been kept under observation. In the last week of July there were 4 cases heard of from Manchester, 3 from Openshaw and 1 from Hulme, all being removed to the Clayton Hospital; and last week 2 other cases were reported in the city. A death from the disease was last week registered at Liverpool, and 2 deaths at Oldham, where the disease is again on the increase, several cases having occurred there and in the adjacent township of Chadderton. The outbreak at Thornhill is causing more anxiety, some alarm having been created by the rapid succession of 4 deaths, and temporary hospital accommodation has been decided upon, as well as the expenditure of £3000 on a permanent structure. Much discontent has been felt at the alleged discharge from the Southport Convalescent Home of a man who was found to be suffering from small-pox. A family of six members has been moved from Stainland, near Halifax, to the Hollins Hey Hospital, and a case has been recorded at the village of Mytholmroyd. In Dublin the news for the week ended Aug. 3rd is to the effect that only 6 cases of small-pox were admitted to hospital, against 15 discharges, leaving only 25 acute cases under treatment, as compared with 36 in the preceding week. Of 3 deaths registered in the week the patients were registered as vaccinated, unvaccinated, and "doubtful as to vaccination." The former and latter were in adult life; the unvaccinated person was aged between five and twenty years.

MALINGERING AND MIRACLES.

A CASE has just been heard at the Paris Assizes which is extremely interesting to the physician, the theologian, and the criminologist. It is that of a man who for some five years or more deceived the greatest physicians in Paris, including Charcot, into believing that he had commencing locomotor ataxy. After having been cauterised and "suspended," neither of which treatments he liked, he eventually arrived at Lourdes, where he was miraculously "cured." In 1891 he robbed the Lourdes fathers of 400 francs, and returning to Paris was admitted to an asylum as suffering from persecution mania, and from this institution he stole some 2000 francs. Being arrested, it was discovered that he was a malingerer of "astounding skill," and was sentenced to four years' imprisonment and ten years' police surveillance. The whole question of modern miracles is an exceedingly difficult one. We should be the last to maintain that they cannot happen, but whether they do is, we believe, queried by Roman Catholic theologians as well as by others. This case of locomotor ataxy may be catalogued along with those which are cured by a certain patent medicine—i.e., the disease never existed; but in this age of unbelief it is a pity when anything occurs to sap the religious element in man. These kind of failures react in a very harmful way upon the hysterical paraplegics who are really ill, if only functionally, and who, if they can only be induced to believe they will be cured, are so, at Lourdes or any other place which has the requisite mystical qualities.

MEDICAL SERVICE OFFICERS AND THE MEDICAL REGISTER.

WE think that Brigade-Surgeon-Lieutenant-Colonel Temple Wright has done a good service to members of the medical departments of the army and navy by calling attention to a subject about which he recently moved a resolution at a general meeting of members of the British Medical Association. The resolution, which was unanimously passed and will be forwarded to the President of the General Medical Council, was this:—

"That this meeting desires to submit a respectful suggestion to the General Medical Council that every medical officer whose name appears in the *Navy List*, the *Army List*, and the *Indian Army List* shall be considered to be still alive and at the post opposite his name."

From the nature of their duties and their conditions of life medical officers of the respective services, unlike civilians, have no fixed place of abode, and are more or less wanderers. It must consequently happen that letters sent to their supposed addresses sometimes fail to reach them, and when this occurs they may find, to their astonishment and possible grave inconvenience, that their names have been struck off the Register under the mistaken assumption, for example, that they are dead. The appearance of their names in the army and navy lists is an official guarantee, however, of their being alive, if not actually present at their respective posts, and may be safely relied upon as correct. Sir Richard Quain had recognised the thoroughly reasonable nature of the representation, and suggested that it should be embodied in a resolution and submitted to the General Medical Council by the British Medical Association, as he very rightly considered that it would materially facilitate the conduct of official business by the Council, of which he is the President. This has accordingly now been done, and Brigade-Surgeon-Lieutenant-Colonel Temple Wright may be fairly congratulated on the practical nature of the step he has taken in the matter.

AN EXHIBITION OF DRUGS AND CHEMICAL PRODUCTS.

PHARMACEUTICAL and practical chemists in general will find interesting material for their inspection at the Drug, Chemical, and Allied Trades Exhibition which is to be held at the Royal Agricultural Hall, Islington, on Sept. 10th, 11th, 12th, and 13th. Whatever may be the pecuniary results of these displays they are undoubtedly most useful in the spreading of correct information with respect to the various articles and processes on view. The experimental chemist is incessantly placing new substances at the disposal of the prescriber, many of whose familiar present-day medicaments were altogether unknown twenty years ago, and pharmacists have not been slack in devising convenient and palatable preparations. The offices of the exhibition are at 42, Bishopsgate-without, E.C.

THE DIAGNOSIS OF SMALL-POX.

A PHYSICIAN with exceptional experience of small-pox and of the common errors of diagnosis in reference to it can do no kinder thing than to give his brethren the benefit of his observation. This is more especially true at a time when the much-dreaded disease threatens to resume activity. The abeyance of the disease for years all over the country, and especially in the metropolis, makes such a communication still more valuable. The growing efficiency of sanitary police checks the spread of small-pox more and more, and makes it possible for many students and even practitioners of medicine never to have seen a case. The effect of vaccination in modifying the disease when it does occur is such as to make an actual case often differ much from the typical case described in books. Under all these circumstances the shrewdest practitioner will be most grateful for a few points of guidance in diagnosis where it is so serious to be wrong and so important to be right. We would direct all that are so minded to a communication in THE LANCET of July 20th by Dr. H. Meredith Richards, medical superintendent of the City Hospitals, Birmingham, whose lot it has been to see not only the 3000 cases sent to the hospitals, but to

Digitized by Google

visit on behalf of the medical officer of health every case notified as "possible small-pox." The points of diagnosis are given with admirable clearness, and not only without any of the airs of superior knowledge, but with ample recognition of the difficulties of the duty and frank admission of the care with which it is generally discharged.

INTERCOLONIAL MEDICAL CONGRESS OF AUSTRALASIA.

WE have received a notice from the secretaries that the date of this Congress has been altered from Feb. 17th to Feb. 3rd, 1896. Another alteration has been made in the arrangements as originally announced in our columns[1] in the formation of a subsection of the Section of Surgery to consider diseases of the eye, ear, and throat. The secretary for this Section is Mr. H. L. Ferguson, High-street, Dunedin. The names of the other secretaries of Sections will be found in our former notice.

THE HONOURS TO THE STAFF OF THE SHAHZADA.

WE note in the daily press that Lieutenant-Colonel A. C. Talbot, C.I.E., has been promoted to the Knight-Commandership of the Indian Empire, and Mr. Thomas Acquin Martin, the Agent to the Government of Afghanistan, has received the honour of knighthood, in recognition of their services during the visit of the Amir's son to England. We cannot but think that the extension of some similar honour to another member of the Shahzada's staff, who is an officer of the Indian Medical Service, would have been appreciated by the medical profession, whose labours on such occasions are too often forgotten. Dr. Leahy must have had to bear the weight of very serious responsibility during the protracted visit of the Prince, and the omission of his name from the list of honours strikes us as an unfortunate and regrettable incident.

AT a meeting of the Strand Board of Guardians held on Tuesday, 13th inst., a resolution was adopted in favour of placing the Salvation Army shelters and all similar institutions under the Common Lodging-house Act, having in view the spread of small-pox and other infectious diseases from these shelters.

SIR E. J. REED has again written to the *Times* expressing a hope that the new Government may see their way to release Dr. Cornelius Herz from the condition of arrest in which he has been for the last two and a half years. The accounts of Dr. Herz's health remain very gloomy.

SOCIETY OF MEDICAL PHONOGRAPHERS.

THE first general meeting of the members of this society was held on July 30th at 20, Hanover-square, London, when there was a very fair attendance of members and visitors, the latter including Sir Henry Howorth, M.P., F.R.S., and Sir William Broadbent. The chair was occupied by Dr. GOWERS, F.R.S., first president and founder, who was supported by Dr. Gray (Oxford), Treasurer, and Dr. Neil, Secretary.

Dr. GOWERS, in his address, stated that the object of the society was to promote the work of their profession, alike in medical science and its application in practice, by freeing it from one grave hindrance which the present has inherited from the past. Writing to-day is what it was when Caxton made it mechanical, with no attempt at improvement until the present generation. But now a method of writing is available in which simplicity of symbol corresponds to simplicity of sound, and which needs, with a greater average of legibility, only one-third of the time and less than one-third of the labour of ordinary writing. Science rests on observation, which without immediate record is of little value; not only is memory inadequate, but record at once reveals unsuspected imperfections in observation. Compared with longhand, shorthand permits in a given time twice the amount of record, while leaving twice the time for observation. The latter must be more minute and more precise to permit the fuller record, and the first effect of the use of shorthand is on the quality of work. The constant use reacts on the worker, and it is again found true that "writing maketh an exact man." In the daily work of the practitioner, which is peculiar in being a form of personal science—knowledge constantly increased by observation—record is most important. It changes vague impression into definite knowledge and increases that ability which is so important to those who suffer. For most practitioners record is practically impossible with longhand; it is possible for all with shorthand. The service of this, however small its influence may be thought, multiplied by numbers, becomes incontestably important. The chief means adopted by the society is the issue of medical literature in lithographed phonetic shorthand—a monthly periodical and other publications. But the facility of writing, and secure legibility, which phonography affords, have led to useful interchange of thought in other ways. The society, started last December, has now 165 members, of whom 25 are students and 140 practitioners. It is important that the student should be familiar with shorthand before beginning professional studies, for it helps him in every form of work. It is much to be desired that shorthand should be made an extra subject in the entrance examination. It needs but a limited and short expenditure of time, and this is soon regained. It can, however, be quickly acquired at any age. It is now taught at many schools, but its subsequent use is not sufficiently encouraged. It may seem strange that the value of this mode of simple writing—quick, easy, and secure—should first be thus recognised by members of the medical profession, but it is noteworthy that, in their hands, its use will probably have most direct influence on the welfare of others.

A letter was read from General Sir C. WILSON, speaking of the recognised value of shorthand to staff officers, and one from Dr. J. H. GLADSTONE, who has used shorthand constantly in science since 1846, and invariably employs it for recording observations and preliminary writing.

The Bishop of HEREFORD wrote: "The establishment of this Society of Medical Phonographers is an event of no small importance. It is obvious that it puts a new instrument into the hands of the observer, an instrument which must be specially valuable when you have to deal with subtle and quickly changing phenomena. I may say how important your action seems to me because of its influence as an example. It will do a great deal to popularise the study in all our higher schools, as it will help to brush away the prejudice that shorthand is chiefly useful for trade purposes and may be neglected by the profession without loss."

Sir HENRY HOWORTH, M.P., F.R.S., in responding to the President's invitation, said he was distinctly one of that class who deplored most desperately that he was not taught shorthand as a boy. In writing his books his great despair and difficulty had been the copying down *verbatim* in the ordinary longhand the material pertinent to the subject. Shorthand would have spared his eyes and saved both time and temper. He felt so strongly on the matter that he was insisting on his boys learning the art. He had travelled in dangerous and difficult countries, where he found one of the greatest difficulties was our cumbrous writing. He referred to the great use made of the art by the President in the compilation of his published works, and went on to speak of the value of the phonetic principle, which had enabled Mr. Reed, at the sittings of the Opium Commission in India last year, to accurately record and afterwards read over the evidence of two Brahmins of whose language he knew nothing and whom he had never seen before. In conclusion he referred to the President as a great evangelist in the cause, and spoke in flattering terms of the *Phonographic Quarterly Review*.

Sir WILLIAM BROADBENT said he was present to testify to his sympathy with the work of the society, and that he agreed with every word of the presidential address. He, also, had to look back with regret to the fact that he did not persevere sufficiently with shorthand to make use of it, but he recognised to the full the utility of the art for taking

[1] THE LANCET, vol. ii., 1894, p. 1115.

Digitized by Google

notes at the bedside. In some cases circumstances prevented the immediate record in ordinary longhand, and when notes were postponed they lost in vividness and accuracy. He looked forward to the time when it would be the rule that all men who seriously worked in the cause of hospitals would make use of such a great advantage. He wished the society success and felt sure it would be extremely useful to the medical profession.

Mr. THOMSON (Dublin), an old shorthand writer, spoke highly of the value of the art in his work and thought the sphere of the society would be extended from day to day. He did not agree that there was an age beyond which shorthand could not be learned, and felt sure that if the last speaker would give a daily hour to the study for a few weeks he would write it with sufficient facility to employ it in private cases.

The PRESIDENT stated that Dr. Landon of Cincinnati, who was forty-five years of age, obtained in a fortnight sufficient power to write a letter which he (Dr. Gowers) could read as swiftly as he could speak.

THE ASSASSINATION OF M. STAMBOULOFF.

WE are enabled, through the courtesy of a medical correspondent at Sofia, to present our readers with some sketches which will enable them to realise the terrible nature of the wounds inflicted upon the late M. Stambouloff better than

FIG. 1.

from the merely printed descriptions which were published at the time. The facts of the outrage are fresh in the memory of everyone. It will be remembered that the deceased statesman was attacked by three men armed with

FIG. 2.

knives and was terribly cut about the head and hands, which he raised to protect his head. Fig. 1, the front view, shows very well an extensive slash (*a*) passing from the right temporal region across the right orbit and the root of the nose to a point on the inner side of the lower border of the left orbit, this being the wound which necessitated the removal of the eyeball. Fig. 2, depicting the wounds on the left side of the face, shows the commencement of the most extensive slash of all (*b*), though not the cruellest in its effect. Starting just above the left eyebrow, it runs back, crossing the middle line at the top of the forehead to end by crossing back again to the left side in the parietal region, as shown in Fig. 4. Fig. 3 depicts the

FIG. 3.

gashes on the right side of the face, which are seen to be much less numerous than on the left, where the temporal and parietal regions were extensively cut about. On the back of the head is a perfect maze of cuts (*b*, *h*, *n*, *m*, *l*, Fig. 4),

FIG. 4.

the horseshoe cut marked (*l*) being particularly extensive. The force with which the blows were given may be inferred from the fact that the skull was fractured in several places.

THE HOLIDAY SEASON AND RAILWAY FACILITIES.

(*Continued from p. 345.*)

AMONG the most useful books published by some of the railway companies, either gratuitously or for the modest sum of one penny, are the lists of country lodgings, farmhouses, &c. Besides those referred to in our article last week we may mention the list published by the Great Eastern Railway Company, giving details of lodgings in Essex, Hertfordshire, Cambridgeshire, Suffolk, and Norfolk. The Great Western Railway Company's list includes Guernsey and Jersey, besides the other places on their lines, and the list of the Great Northern Railway Company embraces Hertfordshire, Cambridgeshire, Huntingdonshire, Northamptonshire, Norfolk, Lincolnshire, Nottinghamshire, Derbyshire, and Yorkshire. The London and South-Western Railway Company's Programme of cheap tickets and general excursion arrangements gives a list of apartments to be let

Digitized by Google

in North Cornwall. Of other books and pamphlets the Great Eastern Railway Company's list is very comprehensive. Visitors to the Continent will find the "Tourist Guide" (price 6*d.*) useful. Small pamphlets on Continental travel are also published. "East Coast Watering-places" gives particulars of time and fare to the watering-places touched by this line. "Summer Holidays in the Land of the Broads" (with descriptive notes and illustrations and a road map), "Holiday Notes in East Anglia," "The Rivers and Broads of Norfolk and Suffolk," and an eight-page pamphlet, "Quiet Nooks on the Norfolk Coast," form exhaustive guides to this part of England. The "Tourist Programme of the Great Northern and North-Eastern Railway Company" gives illustrated and descriptive notes of the east coast route to Scotland, and some useful information is contained in the "Tourist and Excursion Programme of the Great Northern Railway of Ireland." The North British Railway Company issue a "Handy Pocket Guide to Scotland" (price 6*d.*).

Great Eastern Railway.—Until October this company announce cheap tours by the Harwich route to Holland and Germany *viâ* the Hook of Holland, and to Belgium and Switzerland *viâ* Antwerp. For 42*s.* first class and 31*s.* second class a ticket available for a week can be obtained to Amsterdam (exhibition open till October), but they can be used outward only by the Friday or Saturday boat. The return can be made, however, on any day up to and including the following Saturday. To Cologne the first-class return fare is 67*s.* 6*d.*, and the second-class return fare 44*s.* 9*d.* Berlin and back can be done for first class 116*s.*, or second class 81*s.* All the Continental tours by this company are cheap and admirably arranged for the convenience of travellers, as are also the English tours. Of the latter the cheap circular tours by rail and saloon steamboats through the Broads of Norfolk and Suffolk *viâ* the rivers Bure and Yare deserve special mention. Various local tours in connexion with the Broads are also arranged. The various pamphlets issued gratis by the company give full information.

Great Northern Railway.—Tourists' tickets between the stations on this line in England and Scotland are issued till the end of the year at reasonable fares, and every facility is given the traveller for breaking his journey to visit the many places of interest in the country through which this line passes. The "Tourist Programme" contains a long list of tours. On Aug. 17th, 19th, 24th, 26th, and 31st trains leave London and suburban stations from 6.37 A.M. to 7.35 A.M. for Skegness at the return fare of 4*s.* 6*d.* for the day or 6*s.* for a three to four days' trip. Tickets are issued every day for the day trips, but only on Saturdays for the longer periods. Fortnightly tickets are also issued at very cheap fares. The direct express service of this company from England and Wales to Belfast and the principal stations on the Great Northern Railway of Ireland *viâ* Holyhead offers facilities for tourists to visit some of the finest scenery in that country. From the principal Irish towns circular tours are offered, in some cases at very moderate fares.

London and South-Western Railway.—Arrangements have been made with the Western Railway of France for the issue of circular tickets from London to Paris and back available for the return journey within two months. These return tickets are specially applicable to those who propose on their visit to Paris to take a tour through Normandy and Brittany. Tour 1: Waterloo, Southampton, Havre, Rouen, Paris, Versailles, Dreux, Laigle, Argentan, Vire, Pontorson (*viâ* Folligny or Mortain), Mont St. Michel, St. Malo, Jersey, Guernsey, Southampton, London; or returning from Paris *viâ* Versailles, Chartres, Nogent-le-Rotrou, Le Mans, Laval, Vitre, Rennes, St. Malo, Jersey, Guernsey, Southampton, Waterloo. These tickets are also available to go *viâ* Guernsey, Jersey, and St. Malo, &c. to Paris, and to return *viâ* Rouen, Havre, and Southampton to London. First class, 85*s.* 8*d.*; second class, 62*s.* 6*d.* Tour 2: Waterloo, Southampton, Havre, Rouen, Paris, Versailles, Dreux, Laigle, Argentan, Vire, Granville, Jersey, Guernsey, Southampton, London. These tickets are also available to go *viâ* Guernsey, Jersey, Granville, &c. to Paris, and to return *viâ* Rouen, Havre, and Southampton to London. First class, 81*s.* 4*d.*; second class, 59*s.* Passengers holding these tickets are permitted to break their journey at any intermediate station *en route* on the French railway on condition that they present their tickets on arrival to be stamped with the stamp of the station at which they stop. The tickets are available for two months; they can, however, be extended for another month on payment of 10 per cent. on the original cost of the ticket.

Special cheap return tickets are issued from Southampton to Guernsey and Jersey by steamers at 11.45 A.M. and 12 midnight, at the following fares:—Saloon, 20*s.*; fore cabin, 14*s.*, available to return on the following Monday or Tuesday only: saloon, 25*s.*; fore cabin, 17*s.* 6*d.*, available to return on the following Saturday (eighth day), Monday week (tenth day), Saturday week (fifteenth day), and Monday fortnight (seventeenth day). Every Tuesday until further notice cheap return tickets will be issued from Southampton to Guernsey and Jersey by boat at 12 midnight, at the following fares: Saloon, 25*s.*; fore cabin, 17*s.* 6*d.* They are available to return on the following Thursday (third day), Tuesday (eighth day), Thursday week (tenth day), or Tuesday week (fifteenth day).

Fast excursion trains from London to the West of England will run every Friday night during August and September. A special cheap excursion train will run from London to Exeter, Okehampton, Tavistock, Devonport, Plymouth, Barnstaple, Bideford and Ilfracombe, &c., as under:—

The tickets issued by this excursion will be available to return on the following Monday, Saturday week, Monday week, Saturday fortnight, or Monday fortnight following the date of issue.

Great Western Railway.—The pleasure resorts in Dorsetshire, Somersetshire, Devonshire, Cornwall, the Scilly and Channel Islands, Wales, south and east coasts of England, inland watering-places, and Scotland, Ireland, and Paris are all served by this company. Guernsey and Jersey can be reached from London for 38*s.*, including saloon on steamer. The boat train leaves Paddington at 9.15 P.M. daily, except on Sunday, and the passage from Weymouth to Jersey in the express twin-screw mail steamships *Ibex*, *Antelope*, *Gazelle*, and *Lynx* occupies about six hours only.

North British Railway.—The West Highland Railway, one of the extensions of this company, has made easy of access some of the best scenery in Scotland. Among the circular tours announced by this company are: 1. The Trossachs and Lochs Katrine and Lomond *viâ* Edinburgh, Forth Bridge, Dunfermline, Stirling, Aberfoyle, Trossachs, sail on Loch Katrine, coach to and sail on Loch Lomond, Dumbarton (or *viâ* Callander instead of Aberfoyle). Fares:—Edinburgh, first class, 26*s.* 4*d.*; third class, 20*s.* 4*d.*; Glasgow (*viâ* Larbert), first class, 20*s.* 4*d.*; third class, 16*s.* 4*d.* The same tour may be made from Edinburgh *viâ* Linlithgow and Stirling instead of over the Forth Bridge at same fares. 2. Bridge of Orchy, Glencoe, Ballachulish, Port William *viâ* Bridge of Orchy, Glencoe, and Ballachulish, and returning by rail. Fares:—Edinburgh, first class, 42*s.* 4*d.*; third class, 29*s.* 1*d.* Glasgow, first class, 34*s.* 10*d.*; third class, 25*s.* 1*d.* 3. Perth, Dunkeld, Kingussie, Tulloch, Fort William *viâ* Glenfarg, Kingussie, and Tulloch, returning *viâ* Ardlui. Fares:—Edinburgh, first class, 51*s.* 1*d.*; third class, 32*s.* 9*d.* Glasgow, first class, 47*s.* 2*d.*; third class, 30*s.* 6*d.* 4. Aberfoyle, Trossachs, Loch Katrine, Loch Lomond, Fort William, Oban, and Crinan Canal *viâ* Aberfoyle, Trossachs, Inversnaid, and Ardlui, returning *viâ* Oban and Crinan Canal. Fares:—Edinburgh, first class, 48*s.* 2*d.*; third class, 30*s.* 11*d.* Glasgow, first class, 41*s.* 7*d.*; third class, 26*s.* 11*d.*

Digitized by Google

A new night express train with sleeping carriages now leaves Edinburgh (Waverley) daily (Sundays excepted) at 9.30 P.M., reaching London (King's Cross) at 6.20 A.M. Passengers for this train leave Inverness at 3 P.M., Aberdeen at 5.30 P.M., Montrose at 6.29 P.M., Arbroath at 6.53 P.M., Dundee (Tay Bridge) at 7.30 P.M., Perth at 7.55 P.M., Oban at 4.15 P.M., Glasgow at 8 P.M., and Fort William at 3.15 P.M. A train with Pullman sleeping car also leaves Edinburgh for London (St. Pancras) at 9.45 P.M. Passengers from Inverness, Aberdeen, Montrose, Arbroath, Dundee, Perth, Oban, Glasgow, and Fort William leave these places at the times shown above. This train will convey passengers for Manchester, Liverpool, Sheffield, Birmingham, Bristol, London, and for the Midland counties and West of England generally. The 10.30 P.M. train from Edinburgh (Waverley) to London (King's Cross) now leaves at 10.40 P.M. and arrives at London at 8 A.M. Passengers for this train leave Inverness at 3 P.M., Aberdeen at 6.50 P.M., Montrose at 7.45 P.M., Arbroath at 8.9 P.M., Dundee at 8.40 P.M., Perth at 7.55 P.M., Oban at 4.15 P.M., Glasgow at 9.5 P.M., and Fort William at 4.20 P.M. This train has a Pullman sleeping car attached.

London, Brighton, and South Coast Railway.—Among the many tours offered by this company that comprising the whole of the coast between Hastings and the Isle of Wight should prove an attractive one. Monthly tourist tickets from London will be issued every day till the end of October, offering facilities for visiting Hastings, St. Leonards, Eastbourne, Brighton, Worthing, Littlehampton, Bognor, Portsmouth, the Isle of Wight, and almost every intermediate coast-town and village. This tour comprises nearly 300 miles of the most charming railway and steamboat travelling in the United Kingdom. The journey may be made from London Bridge, Victoria, or Kensington, and can be taken either way, going first to Hastings and thence by the South Coast line to Portsmouth, proceeding from Portsmouth by mail steamers to Ryde, and returning from Portsmouth, terminating the trip at any stopping station of the London, Brighton, and South Coast Railway between Portsmouth and London, or reversing the route by going first to Portsmouth, and returning by Brighton, Hastings, &c. For the whole round (exclusive of pier dues at Ryde) the fares are—first class, 37*s.*; second class, 27*s.*; third class, 18*s.* Tickets are available for all trains, and can be had at London Bridge or Victoria Stations, and at the West-end offices, 28, Regent-street, Piccadilly, and 8, Grand Hotel-buildings, Trafalgar-square; also at Cook's Tourist Office, Ludgate-circus, and Gaze's Tourist Office, 142, Strand. The tourist and excursion programme gives details of various Continental tours, including a most comprehensive list of Italian tours.

London, Chatham, and Dover Railway.—This company offer some cheap excursions to the watering-places along the north and north-east coast of Kent. The week-end trips to the north of France, which run every Friday, Saturday, and Sunday, will be found convenient by those who can only spare a few days. The tickets are available for return by any boat and train up to and including the 3.45 P.M. service from Calais on the Monday following date of issue. Trains leave the London stations shortly after 8 P.M. on Fridays and Saturdays, and 9 A.M. on Saturdays and Sundays, arriving at Calais about noon and midnight respectively. Return fares 31*s.*, 26*s.*, and 20*s.* Third-class tickets are not issued for the morning service. Quick services are announced for Switzerland and Italy.

The *Cambrian Railways* issue an excellent programme of rail and coach excursions to places of interest adjacent to their lines in wild and picturesque Wales. First and third class tourist tickets, available for two calendar months, renewable up to Dec. 31st, are issued to Oct. 31st at all the principal stations in England, Scotland, and Ireland to Aberystwyth, Borth, Machynlleth, Aberdovey, Towyn, Dolgelley, Barmouth, Harlech, Portmadoc, Criccieth, Pwllheli, Rhayader, Builth Wells, and Brecon. The scenery traversed by and adjacent to the Cambrian Railways is of an exceedingly varied and beautiful description, and the coast of Cardigan Bay, to which the line affords the most convenient access, offers great advantages for sea-bathing in the long reaches of firm, safe, and sandy beach with which it abounds. The air is pure and bracing. The mountain ranges of Snowdon, Cader Idris, Plinlimmon, and the Beacons, with their rivers and lakes, are also readily accessible from the various watering-places, thus placing within the reach of visitors a delightful combination of the natural beauties of sea and land. The Upper Valleys of the Wye, the Severn, and the Usk, through which the line to Brecon runs, also possess great attractions for tourists and anglers. Arrangements are made during the summer months for the conveyance of visitors by coach to and from places of interest in the vicinity of the line at reduced charges, by which means, and also by the Festiniog, Tal-y-llyn, and Corris miniature gauge railways, whose termini are on the Cambrian system, the following amongst other places can easily be visited by daily excursions:—Snowdon, Beddgelert, Tan-y-bwlch, Maentwrog, Festiniog, Slate Quarries, Cader Idris, Mawddach Estuary, Precipice Walk and Torrent Walk, Tyn-y-groes, Pistyll-y-Caen, &c. (Dolgelley), Taly-y-llyn Lake, Corris, Llyfnant Valley, Glaspwll Cascade, Rheidol Lake, Devil's Bridge, Abersoch, Nevin, Clynnog, Nantgwillt (the site of the new Birmingham Water Works), Happy Valley, Cwmbychan Lake, Drws Ardudwy, Rhenig Valley, Dinas Mawddwy, and Bwchoerddrws Pass. About thirty rail and coach excursions daily are run from the Cambrian stations during the season. An excellent feature of the Cambrian Railways is the issuing of cheap weekly season tickets for 15*s.* third class, and 25*s.* first class, enabling the holders to travel by any trains between all the coast stations, including Machynlleth and Dolgelley.

THE FATAL ATTACK ON THE SON OF A MEDICAL MAN AT LIVERPOOL.

THE poor boy William Ireland, the son of Mr. R. J. Ireland, M.R.C.S., L.R.C.P. Irel., of Walton, Liverpool, who is alleged to have received terrible injuries at the hands of a Mr. O'Callaghan, described as a medical man and Mr. Ireland's assistant, on the night of Thursday, Aug. 8th, died early last Wednesday morning, five days after his injuries were inflicted. We need not dilate on the circumstances of the crime, and as the alleged murderer is now under remand all speculation as to his measure of guilt would be obviously unbecoming. There is no certainty about the weapon with which the abdominal wound was made or of the means by which the boy received his other injuries, though it seems probable that the gash through which the bowels protruded was made by a piece of broken glass from a dressing-mirror which was smashed, and which to all appearance would have inflicted just such a wound. The site of this gash was a little internal to and above the anterior superior iliac spine on the left side. It was a jagged, irregular wound about two inches long in its greatest diameter, which was towards the chest. The abdominal planes of muscle beneath were irregularly divided in a situation slightly superior to the skin wound, and the peritoneum divided a little superior again to the division of the muscles, so that the cavity of the abdomen was opened in a valvular manner, the tract of the opening slanting upwards through the abdominal wall. Three feet of small intestine had escaped from the wound, a result which is accounted for by the fact that some delay elapsed between the infliction of the injury and the arrival of the poor child at the Bootle Borough Hospital, whither he was taken on being found by the police to have received these serious injuries. As a result of exposure the gut was covered with fluff and dirt. The hernia was immediately cleaned by the senior house surgeon, Mr. H. B. Dickinson, and reduced into the abdomen, the wound dressed and a drainage tube inserted. During the dressing on the following day a small piece of gut which presented at the opening in the peritoneum was observed to be turning black. This was accordingly brought slightly out of the wound, and when adhesions were formed, opened and an artificial anus established in the usual way, the operation being performed by Mr. James Pearson, surgeon to the hospital. The boy, who was an exceptionally hardy little fellow of about twelve years of age, survived till the following Wednesday morning, but never really flattered his medical attendants with any hope of recovery. Although the abdominal wound was the injury that must be looked upon as the cause of death, he was also bruised all over, having one large bruise on the forehead, another one on the right cheek; the lobe of the right ear was torn up from the face, there was an irregular and jagged cut on the left side of the neck, a large bruise on the penis, and
